## PNEUMONIA IN PRIVATE PRACTICE

A STUDY OF 911 CASES

RUSSELL L. CECIL, M.D.

AND

EDGAR A. LAWRENCE, M.D.

NEW YORK

Much has been written in recent times concerning pneumonia especially as regards the incidence of the various types of pneumococcic pneumonia and their amenability to serum therapy. When compared, these reports have shown a rather striking consistency both in the incidence of pneumococcus types and in the results obtained with specific treatment. However, these studies have been based largely on material observed in large city hospitals such as Bellevue and Harlem hospitals in New York and the Boston City Hospital. So far as we know, there have been no modern studies published on pneumonia in private practice. The impression seems to be general, however, that the death rate for pneumonia in private practice is considerably lower than it is in large city hospitals. While in hospital wards the fatality rate may run from 30 to 35 per cent, one often hears practitioners assert that in private practice they rarely lose a patient with pneumonia, and Osler, quoting Howard and Fussell, states that the fatality rate in the latter group varies between 6 and 17 per cent.<sup>1</sup>

In the hope of throwing some additional light on this subject, we have collected 911 cases of pneumonia from private practice. The number of cases included is not as large as we should have liked it to be, but at least it is large enough to form a basis for certain general conclusions.

This study falls naturally into three divisions: (1) patients treated at home, (2) patients treated in the private pavilions of hospitals, and (3) patients seen in consultation in private practice.

### PATIENTS TREATED AT HOME

Our original intention was to collect the material for this study from all three of the sources mentioned. We found it almost impossible, however, to obtain adequate records on patients who had been treated in the home. Through the kindness of Dr. Edward S. Rogers, director of the New York State Bureau for Pneumonia Control, we are able to quote the following figures from his investigations in New York State: Rogers found that in 1,475 hospital cases of pneumococcus type I pneumonia the fatality rate was 18.5 per

cent, whereas in 551 cases of the same type in which treatment was given in the home the death rate was only 13.4 per cent, a difference of 5 per cent. All the patients in both series received type I serum. These patients were not citizens of New York City but were collected from cities, towns and rural districts in New York State excluding New York City.

The factors that may influence this difference in the fatality rate of patients treated in the hospital and those treated at home will be discussed later.

### PATIENTS FROM THE PRIVATE PAVILIONS OF HOSPITALS

The greater part of the material for this study (560 cases) was obtained from the private wards of New York City hospitals. These patients were all admitted during the last decade (1928-1938) and all had been "typed" by standard methods. Many cases of typical lobar pneumonia (more than 50 per cent) had to be excluded from our survey because of inadequate bacteriologic study. The hospitals whose records were used in the compilation were the Doctors' Hospital, Fifth Avenue Hospital, Mount Sinai Hospital, New York Hospital, Post-Graduate Hospital, Presbyterian Hospital and Saint Luke's Hospital, all in the city of New York.<sup>2</sup>

**Bacteriologic Classification.**—In table 1 it will be noted that approximately 95 per cent of the cases of pneumonia in this series are of pneumococcic origin. This agrees very closely with the observations of Cecil, Baldwin and Larsen<sup>3</sup> in their statistical study of 2,000 cases of pneumonia at Bellevue Hospital and with the results reported by the workers from Rockefeller Institute.<sup>4</sup> In all these studies, *Streptococcus haemolyticus* pneumonia ranks second in prevalence, averaging about 3 per cent of the total series.

**Age and Sex Distribution.**—The most important fact brought out in this connection was that the average age in this series of 560 pavilion patients was 45 years, whereas the average age in our Bellevue studies was only 38 years. The sexes were about equally represented, in contrast to studies made in city hospitals, in which the males have far outnumbered the females. In the present study 53.6 per cent were males and 46.4 per cent females. In the Bellevue Hospital studies 83.1 per cent were males and 16.9 per cent females.

**Incidence of the Various Types of Pneumococcic Pneumonia.**—Table 2 shows the incidence of the dominant types of pneumococcic pneumonia. Type III pneumonia was the most prevalent (20.2 per cent). In

this respect the present series differs sharply from previous studies, in which type I has been the commonest type. This difference in type distribution can be explained at least in part by the higher age incidence of pneumonia in private patients. The studies by Cecil and his co-workers<sup>5</sup> at Bellevue Hospital showed clearly that the incidence of type III pneu-

the ages of 20 and 40; of type III, after the age of 60, in contrast to the Bellevue figures, which show that the highest incidence of type I occurred between the ages of 20 and 30, and of type III between 30 and 50.

**Clinical Characteristics.**—The various forms of pneumonia showed the characteristics that have been described in previous studies. Cases due to pneumococci of types I, II and III were nearly always typical lobar infections with classic history, frank physical signs and rusty sputum. The seriously ill patients usually showed signs of multilobar involvement. The "miscellaneous" types often presented an atypical picture, with only partial consolidation of the lobes and purulent rather than bloody or rusty sputum. The patients with streptococcal or staphylococcal infections were, almost without exception, seriously ill but with indefinite signs in the chest.

**Bacteremia.**—Unfortunately, blood cultures were not taken as a routine in this group of patients. However, 287 patients were subjected to blood cultures, and the results are shown in table 3.

Approximately 24 per cent of the patients in this series yielded positive blood cultures, and in the septic cases the fatality rate was 74 per cent. Patients with negative blood cultures showed a fatality rate of only

Incidence and fatality rates for pneumococcus types in relation to age (private pavilion series).

monia increases with age, an observation which has been corroborated by Blake<sup>6</sup> and others.

In table 2 one also notes a very high incidence of the miscellaneous types (57.3 per cent), much higher than in most of the series reported from other institutions. Whether this was actually the case or whether the typing was inaccurate it is impossible to say. The newer types have not been separately listed in table 2, as they were recognized only during the last few years of the period covered by the study.

TABLE 1.—Bacteriologic Classification of 560 Cases of Pneumonia from Private Pavilions

Bacteria	Number of Cases	Incidence, per Cent
<i>Pneumococcus</i> (all types).....	531	94.8
<i>Streptococcus haemolyticus</i> .....	19	3.4
<i>Streptococcus viridans</i> .....	2	0.35
<i>Bacillus influenzae</i> .....	1	0.2
<i>Staphylococcus aureus</i> .....	4	0.7
<i>Staphylococcus albus</i> .....	1	0.2
<i>Friedländer's bacillus</i> .....	2	0.35
Total.....	560	100.00

TABLE 2.—Incidence of *Pneumococcus* Types in Private Pavilion Series

Type of <i>Pneumococcus</i>	Cases	Incidence, per Cent
<i>Pneumococcus</i> type I.....	83	15.6
<i>Pneumococcus</i> type II.....	37	6.9
<i>Pneumococcus</i> type III.....	107	20.2
Miscellaneous types (group IV).....	304	57.3
Total.....	531	100.0

It is noteworthy that 78.4 per cent of the cases of type II pneumonia occurred in the male and only 21.6 per cent in the female.

In 531 cases of pneumococcal pneumonia in private pavilions, the incidence of type I was highest between

6. Blake, F. G.: Observations on *Pneumococcus* Type III Pneumonia, Ann. Int. Med. 5: 673-686 (Dec.) 1931.

TABLE 3.—Blood Cultures in the *Pneumococcus* Series

Type of <i>Pneumococcus</i>	Positive Blood Cultures		Negative Blood Cultures	
	Number	Fatality, per Cent	Number	Fatality, per Cent
Type I.....	12	8	35	5
Type II.....	4	3	19	1
Type III.....	26	21	47	20
Miscellaneous types	27	19	114	9
Total.....	69	51	218	35

16 per cent. However, the figure was unusually high (42.6 per cent) for forty-seven patients with type III pneumonia with sterile blood cultures.

**Complications.**—Analysis of the complications encountered in the series reveals nothing especially noteworthy. Empyema was the most prevalent complication, showing an incidence of 5 per cent in the pneumococcus series and 26.3 per cent in the cases of streptococcal pneumonia. Type I pneumonia showed an empyema incidence rate of 8.7 per cent. Endocarditis, meningitis and pericarditis were rarely reported. Fibrillation developed in quite a number of the older patients and was usually followed by a fatal termination.

**Fatality Rates.**—We were particularly interested in determining the fatality rate for patients in the private pavilions. Figures for the various types of pneumonia are recorded in table 4. Cases in which specific therapy was given are omitted. The death rate for pneumococcal pneumonia without serum therapy was 30.1 per cent, a figure which is generally looked on as about the standard for type I pneumonia without serum therapy. For example, Heffron's<sup>7</sup> figures on 2,047 cases of type I pneumonia in the United States and Canada in which serum therapy was not given showed a fatality rate of 30 per cent.

The fatality rate for *Streptococcus haemolyticus* pneumonia (47.4 per cent) approximates closely previous figures in the literature.<sup>8</sup>

7. Heffron, Roderick: Final Report of the Massachusetts Pneumonia Study and Service 1931-1935, Commonwealth 24, January-February-March 1937.

8. Bullowa, J. G. M.: Management of the Pneumonias, New York, Oxford Medical Publications, 1937.

The fatality rate for the entire group of 450 cases is 31.7 per cent, which checks pretty closely with the fatality rates for the wards of large city hospitals.

*Fatality Rates for Various Pneumococcus Types.*—The fatality rates for the dominant types of pneumococcic pneumonia are indicated in table 5 and are compared with similar figures from the series previously

TABLE 4.—Fatality Rates in Relation to Bacterial Etiology

Bacteria	Number of Cases	Deaths	Fatality, per Cent
<i>Pneumococcus</i> (no serum).....	421	127	30.1
<i>Streptococcus haemolyticus</i> .....	19	9	47.4
<i>Streptococcus viridans</i> .....	2	1	50.0
<i>Bacillus influenza</i> .....	1	0	0.0
<i>Staphylococcus aureus</i> .....	4	4	100.0
<i>Staphylococcus albus</i> .....	1	1	100.0
<i>Friedländer bacillus</i> .....	2	1	50.0
Total.....	450	142	31.7

TABLE 5.—Comparison of Fatality Rates Between Private Pavilion Series and Bellevue Hospital Series

Types of Pneumococcus	Present Series (No Serum)			Bellevue Hospital (No Serum)		
	No. of Cases	Deaths	Mortality, per Cent	No. of Cases	Deaths	Mortality, per Cent
Type I.....	31	10	32.0	234	73	31.2
Type II.....	23	7	30.4	441	215	48.8
Type III.....	102	56	54.9	500	210	42.0
Miscellaneous	265	54	20.4	373	109	29.2
Total.....	421	127	30.1	1,548	607	39.2

reported by one of us from Bellevue Hospital.<sup>3</sup> The fatality rates for pneumonia at Bellevue Hospital are proverbially high, but it will be seen from table 5 that the rates for our private pavilion series are not so far below them. Indeed, the fatality rate for 102 cases of type III pneumonia in the private pavilion series is considerably higher than that for a similar series at Bellevue.

As in all previous studies, the fatality rate for the various types increases with the age of the patient, as shown in the accompanying chart.

*Results with Serum Therapy.*—It is interesting to note that in only 60 per cent of type I cases in the private pavilion series was type I serum given. In the type II cases an even smaller proportion was given the benefit of specific therapy. In the newer types it was not to be expected that a high proportion of the patients would receive serum therapy because of the difficulty in many instances of obtaining the serum. However, in view of the well established efficacy of type I serum, it is difficult to understand why so many physicians withheld serum therapy from their type I cases.

Furthermore, the results obtained in fifty-two cases of type I pneumonia in which serum therapy was given were not so favorable as those which have been reported by various observers from large city hospitals such as Bellevue, Harlem<sup>9</sup> and the Boston City Hospital.<sup>9</sup> The reason for the high figure in the present series is easily discovered: In too many cases the serum treatment was initiated quite late in the disease.

Thirty-five patients with type I pneumonia were treated with serum during the first three days of the disease. In this selected group the fatality rate was only 14.3 per cent. In twelve cases of type II pneu-

monia in which serum therapy was instituted during the first three days there was only one death (8.3 per cent).

It must also be remembered that the average age in this series of patients is almost a decade higher than that reported in studies from various city hospitals. This factor must certainly be considered in comparing the results of serum in the present study with the results obtained elsewhere.

The value of serum therapy for the newer types, especially types V, VII and VIII, has been pretty well established by Bullowa,<sup>10</sup> Finland and Tilghman<sup>11</sup> and others. The results of serum treatment for the new types are well summarized by Lord and Heffron<sup>12</sup> in their recently revised monograph on pneumonia and serum therapy. In the present study the results with serum therapy in these types (table 6) were certainly encouraging, though the number of patients treated was too small to have much significance.

A few of the patients in this series received anti-pneumococcus rabbit serum. The number of patients, however, was not large enough to justify any inferences concerning its relative value as compared with horse serum. It is interesting to compare the total of 107 cases of all types in which serum was given with 221 cases in which none was given. The fatality rate in the group in which serum was given was approximately half of that for the group in which no serum was given (20.5 per cent versus 38.4 per cent).

PATIENTS SEEN IN CONSULTATION

In addition to the 560 cases studied in the private pavilions of hospitals, we have collected from our personal records 351 cases of pneumonia which were seen

TABLE 6.—Results of Serum Therapy in 107 Cases of Pneumonia from Private Pavilion Series

Types of Pneumococcus	Treated with Serum			Untreated		
	No. of Cases	Deaths	Mortality, per Cent	No. of Cases	Deaths	Mortality, per Cent

only in consultation. The data obtained in these cases are naturally not as complete as those derived from the hospital charts of the private pavilion patients.

12. Lord, F. T., and Heffron, Roderick: Lobar Pneumonia and Serum Therapy, Commonwealth Fund, 1936.

However, every case seen in consultation was followed up for information concerning termination, complications and the like. Only cases in which the type of bacterial infection was definitely established are included in this group.

*Age and Sex Distribution.*—In the consultation series the average age and sex distribution was approximately the same as that noted in the private pavilion series.

*Distribution by Type.*—In table 7 the varieties of pneumonia are shown. The figures differ somewhat from those already presented for patients in private pavilions. In the consultation series the percentage of cases of pneumococcic pneumonia is lower and the incidence of cases of streptococcic and staphylococcic pneumonia is twice as high as in the private pavilion series. This difference was to be expected in a group of serious cases, such as those composing the consultation series.

*Incidence of Various Types of Pneumococcic Pneumonia in Consultation Series.*—In table 8 it will be noted that the incidence of the prevalent types of pneumococcic pneumonia does not differ widely from

than that for type III pneumonia (40 per cent) in city hospital clinics. Here again we must recall the age of the patients. One of the commonest types of patient encountered in consultation practice is the elderly patient with type III pneumonia, and a very high percentage of them die.

The fatality rate is also very high for the Streptococcus haemolyticus infections (50 per cent) and runs up to 100 per cent in the series of Staphylococcus aureus pneumonia (ten cases).

The fatality rate for patients with positive blood cultures was 70 per cent as compared with 42 per cent for patients with sterile blood cultures. A considerable number of patients with type III pneumonia died without developing sepsis, as in the pavilion series.

*Serum Therapy.*—Sixty-three patients with type I pneumonia received type I serum (table 9), with a fatality rate of 23.8 per cent, a figure practically identical with that for the serum treated patients in the private pavilion series. This rate is much too high for serum treated type I infections. In most of the large series studied from city hospitals the death rate for serum treated type I pneumonia has varied from 10 to 16 per cent.

The results of serum therapy in this series has been disappointing, chiefly because in nearly all cases the infections were severe to begin with, but more important still because many of these patients received serum late in the disease. For example, the death rate for sixty-three patients with type I infection who received serum was 23.8 per cent, while for sixteen patients who received no serum there was a fatality rate of only 25 per cent. However, for forty patients who received type I serum during the first three days of the disease there was a fatality rate of only 17.5 per cent. An analysis of the cases that were fatal in spite of serum treatment makes it quite obvious in most instances why the patient was not saved by the specific serum. For example, seven patients were treated after the fifth day and one patient was treated as late as the fourteenth day. Two patients had insufficient serum, one receiving only 6,000 units. Two patients died of pulmonary embolism after they had recovered from pneumonia. Two more were elderly alcoholic addicts.

What has been said concerning the type I cases applies equally to the type II series (table 9). The serum treatment again made a poor showing in a small group of cases. The number of cases of the higher types in which specific serum therapy was used is too small to be significant.

COMMENT

This study has provided a considerable amount of information concerning pneumonia in private practice. Of prime importance is the fact that the social stratum of the patient has little to do with the prognosis, which depends not so much on the economic status of the person as on his age, on the type of pneumonia and, most important of all, on the availability and early use of serum. With regard to the cost of antipneumococcus serum, its efficacy has now been so clearly proved that it should be supplied free by state and city boards of health, as is the case, for example, in the city and state of New York. It would appear from Rogers' figures that the death rate for pneumonia is lowest among patients who receive treatment at home. We imagine that the same will be found to be true in a similar study now being made by the health department in the city of New York.

TABLE 8.—Incidence and Fatality Rates of Pneumococcic Pneumonia in Consultation Practice (Serum Treated and Non-Serum Treated Combined)

Type of Pneumococcus	No. of Cases	Incidence, per Cent	Deaths	Mortality, per Cent

Type I.....	63	15	23.8
Type II.....	27	13	48.1
Type III (rabbit serum).....	2	1	50.0
Miscellaneous types.....	16	5	31.3

that observed in the private pavilion series. Type III and the miscellaneous types compose a large percentage (65.6 per cent) of the group, just as in the private pavilion group.

*Complications.*—In this series of consultation cases, most of them severe infections, one would expect a rather high incidence of complications, and such proved to be the case. Empyema occurred in 12.6 per cent of all cases of type I pneumonia, with a death rate of 29.9 per cent, endocarditis in 1.1 per cent and meningitis in 0.85 per cent of all cases. Most of these consultation cases were seen in the home, with the family physician, and it is quite likely that a certain number of complications, such as terminal empyema, endocarditis and meningitis, were overlooked for lack of x-ray and other laboratory facilities.

*Fatality Rate.*—The case fatality rate for the entire series of consultation cases, including all types, both serum treated and non-serum treated cases, was 41 per cent, a very high rate and one that clearly indicates the serious prognosis in the group under consideration (table 7). In table 8 the case fatality rates for the dominant pneumococcus types are indicated. One is impressed with the high fatality rate for type III pneumonia, 59.5 per cent, which is considerably greater

One should not infer from this, however, that patients receive better treatment at home than they do in the private pavilions of hospitals. Nor should the inference be made that transportation in an ambulance is a detriment to the patient's chance of recovery. The Rockefeller Institute's statistics on pneumonia have always been among the best; yet practically every patient in their records was admitted by ambulance. The most plausible explanation is that the practitioner sends his sick patients to the hospital but allows his patients with mild attacks to remain at home. Certainly this seems the most rational explanation of the difference in death rates between home and hospital cases. At this point one may well raise the question of the proper disposition of the pneumonia patient in private practice. Should he be treated at home or should he be transferred to a convenient hospital? In answer to this question, several factors have to be taken into consideration:

1. Has the patient a comfortable home with proper facilities for handling the sick?
2. Does the patient live in town and at a convenient distance from the doctor's office or does he live in the country where he is inaccessible to emergency care?
3. Is the hospital under consideration provided with a medical house officer who is capable of handling medical emergencies such as vasomotor collapse, cyanosis or pulmonary edema?

There are certain obvious advantages in having a pneumonia patient under hospital care. The most important of these are that a clinical laboratory where sputum and blood cultures can be frequently examined is accessible; x-ray examinations are conveniently made; a house officer is usually available to handle any emergency that develops; oxygen therapy can be more readily supervised; serum treatment can be given at regular intervals, a procedure which is difficult to carry out in the private home, and, finally, if a surgical emergency arises, treatment can be promptly initiated.

Several facts brought out by this study are worthy of further comment. The fact should be stressed that the average age incidence of pneumonia among the well-to-do classes is almost a decade higher than that of pneumonia in the wards of large city hospitals. Pneumonia at Bellevue Hospital is a disease of young working men; pneumonia in private practice is a disease of the middle aged and elderly.

Certainly one of the most interesting facts elucidated has been the very high incidence and death rate of patients in private practice with type III pneumonia. Type III pneumonia, by reason of its prevalence and fatality rate of almost 60 per cent, has come to be one of the most serious problems that the practitioner has to face. It is made doubly serious by reason of the apparent failure of type III serum to control the infection.

It was disappointing to find so many histories of private patients with pneumonia in the hospital files with no record of any bacteriologic study. However, this investigation covers a period of ten years. During the last five years, sputum typing and blood cultures have been carried out in a much higher percentage of cases. This applies also to the use of antipneumococcus serum in the treatment of type I pneumonia. Only 60 per cent of the patients with type I pneumonia in the private pavilion series received type I serum. However, the percentage of cases in which serum therapy was used is definitely higher for the last five years of the study than for the first five years. With respect to the series of 351 cases of pneumonia in the con-

sultation series, the fact should be stressed that we are dealing here with a group of very ill patients. The fatality rate in this group was quite high for every type. The lesson to be derived from a study of this group is that consultations should be held early in the disease, when special therapy such as oxygen and serum will be of most value to the patient.

Pneumonia in private practice is not so mild a disease as it has often been considered to be. Certainly in New York private hospital pavilions the fatality rate is surprisingly high—no doubt definitely higher than the rate for small towns and rural districts.

We regret that we cannot speak with more authority concerning the value of serum in the treatment of the newer types of pneumonia. Our impressions have been quite favorable, particularly in the serum treatment of types V, VII and VIII, but the number of cases observed is too small to have statistical value.

We have omitted statistical data on the dosage of serum administered, since accurate details were not always available from the patient's chart. In nearly every case the serum employed has been of the concentrated and refined type of horse serum first described by Felton. The new method of giving serum in large single intravenous doses of from 100,000 to 150,000 units seems to have no deleterious effects when given very slowly, but we agree with Lord and Heffron that it is still wiser for the general practitioner to administer serum in frequent divided doses.

Only fifteen patients in our entire series were treated with antipneumococcus rabbit serum. Because of the small number of cases in this group, we have refrained from drawing any conclusions. However, apart from the fact that rabbit serum is available for some types for which there is at present no horse serum (types VI, XVII, XVIII and so on) we have found no noteworthy difference either in the course of the disease or in the incidence of complications when compared with those treated with refined horse serum. In a patient with type III pneumonia who received approximately 850,000 units of concentrated type III rabbit serum early in the disease there developed, several days after administration of serum, a pneumococcus type III empyema necessitating resection of a rib.

#### SUMMARY

1. Nine hundred and eleven cases of pneumonia from the records of private practice were reviewed with special reference to the incidence and fatality rates for the various types and the results of serum therapy.
2. The data obtained from the "private practice" series were compared with well established data based on pneumonia records from the public wards of large city hospitals.
3. The most significant facts brought out by this comparative study are:
  - (a) The generally higher age incidence of pneumonia in the well-to-do classes.
  - (b) The high incidence of type III pneumonia in private practice. This probably results in part from the higher age incidence of this group.
  - (c) Inadequate bacteriologic study of the "private pavilion" cases. Less than half of the patients available for study had been properly typed.
4. Only 60 per cent of the private pavilion patients with pneumococcus type I infections received type I serum. In the "consultation series" a much higher proportion received serum. The results of serum therapy in both series were not as favorable as those obtained

in the general wards of large city hospitals; the fatality rate of 23.5 per cent for the entire series of 115 cases of type I pneumonia in which serum therapy was given is almost double that reported from various other sources and is not conspicuously lower than the standard fatality rate (30 per cent) for type I non-serum treated cases. A number of factors, such as the higher age incidence, the severity of the cases studied, delay in administering serum, or inadequate dosage are probably responsible for this high figure.

5. Pneumonia in private practice is not so mild as it has often been claimed to be. In view of the well demonstrated value of specific therapy in pneumonia, administration of serum should be part of the routine treatment in every case amenable to such therapy, regardless of the social status of the patient.

## THE TOXEMIAS OF PREGNANCY

TREATMENT BASED ON A NEW CONCEPT  
OF THE ETIOLOGY

F. L. McPHAIL, M.D.

GREAT FALLS, MONT.

A new concept of the physiology and pathology underlying the development of the toxemic state in pregnancy is based on old and new knowledge of the role of body fluids in maintaining the integrity of the organism. A method of treatment is derived from this concept in the light of facts developed in connection with studies on water balance, acid-base equilibrium, renal function and shifts in body water and electrolyte.

Newburgh<sup>1</sup> and his associates have measured water exchange in many persons with normal and abnormal renal function. They found that if the intake of water was restricted in cases of impaired renal function, retention of urinary solids would result. If large amounts of water were given, the quantity of urinary solids excreted would be comparable to the excretion by a normal person ingesting the same diet. From these data they were able to calculate the amount of urinary water necessary to remove definite quantities of urinary solids. As the concentrating ability of the kidneys lessened, more urinary water was necessary to remove the urinary solids.

Fluid is held within the body in two main chambers, the extracellular and the intracellular compartment. The cells of the body are surrounded by interstitial fluid. This fluid carries nourishment to, and waste away from, the cells. It also controls the temperature of the organism and maintains osmotic equilibrium and a stable hydrogen ion concentration.

The fluid contained in an organism amounts to approximately 70 per cent of the body weight. The extracellular fluid accounts for 20 per cent and the intracellular for 50 per cent. The extracellular fluid

is composed of the blood plasma 5 per cent and the interstitial fluid, including lymph, 15 per cent of the body weight. In a person weighing 150 pounds (68 Kg.) the body fluid would be distributed approximately as in table 1.

Darrow and Yannet<sup>2</sup> found that when there was an increase in extracellular electrolyte there was a shift of body water from the cells to the extracellular fluid but that when there was a decrease in extracellular electrolyte there was a shift of water from the extracellular fluid into the cells. They pointed out that, as nine tenths of the osmotic pressure of body fluids is maintained by electrolyte, the shift of body water is largely governed by the distribution of electrolyte.

When urinary solids are retained there is an accumulation of both urinary waste and electrolyte in the blood plasma. It then becomes necessary for the organism to make adjustments to maintain osmotic equilibrium and to keep the hydrogen ion concentration within normal limits if normal metabolic activity is to persist. Small molecules and inorganic ions pass readily across the capillary membrane into the interstitial spaces. The interstitial fluid, in order to maintain osmotic equilibrium with the intracellular fluid, draws water from the cells. Darrow and Yannet<sup>2</sup> emphasized the fact that, when the concentration of electrolyte in the extracellular fluid is altered, serious symptoms can follow the shift of body water from the cells to the extracellular fluid even though the total body water is unchanged.

Gamble<sup>3</sup> pointed out that in considering electrolyte one deals not with salts but with separately controlled concentrations of anions and cations. Therefore when retention of urinary solids is present a consideration of the food ingested is of great importance. The average diet composed of liberal quantities of milk, fruits and vegetables yields a basic ash. If when retention occurs the diet ingested yields a basic ash, there will be an increase of base in the blood plasma. Ordinarily the kidneys control the amount of base in the blood, but if renal function is hampered and excess base is not eliminated the excess base must move out of the blood plasma into the interstitial fluid to preserve a normal hydrogen ion concentration. This shift produces edema, or swelling, of the interstitial spaces, and shrinking, or dehydration, in the cells.

If the diet yields an acid ash and the excess ions cannot be excreted, the lungs will dispose of carbonic acid, thus keeping acid and base in balance. Clinical edema will not be noted. This protective mechanism alters the composition of the blood plasma, and gradually an important buffer, bicarbonate, is depleted and replaced by acid ions which should have been excreted. A serious toxemia, with no appreciable edema, may develop.

Newburgh<sup>4</sup> has developed a diet the ash of which gives a neutral reaction. By using this diet he is able to supply ample food without disturbing the delicate acid-base balance.

### THE TOXEMIAS

It is believed that toxemia will not develop if no impairment of renal function exists. The impairment may be so slight that no test yet developed will point

From the Great Falls Clinic.

it out. However, when the burden of fetal excretion is added without a sufficient increase in fluid intake there may be a retention of urinary waste and electrolyte. As the blood plasma is not able to rid itself of these retained products it becomes hypertonic. In order that osmotic equilibrium may be retained there must then be a shift of water from the reservoir of the body, the intracellular compartment. This shift of water will at first aid in the excretion of some of the retained solids; but, as the retention increases, some of the small molecules and inorganic ions will pass into the interstitial spaces. More water is then drawn from the cells to maintain osmotic equilibrium with the surrounding fluid.

The changes within the body will be influenced by the reaction of the residue after the food is burned. A diet yielding an alkaline ash will produce a shift of water from the cells to the interstitial spaces. The result is cellular dehydration and edema. If the diet yields an acid ash, water will be drawn from the cells to increase the urinary output. The result is an increased concentration in the intracellular and extracellular fluid. In both instances metabolic activity is altered by increased concentration within the cells.

#### TREATMENT OF THE TOXEMIAS OF PREGNANCY

Newburgh<sup>1c</sup> demonstrated that impaired kidneys could be made to excrete the normal amount of urinary solids if large amounts of fluid were ingested. Treatment of the toxemic patient must vary for the non-convulsive and the convulsive type, yet the basic principle remains the same. To overcome the retention of urinary solids large quantities of fluid must be ingested. As fluids are taken liberally the blood plasma becomes hypotonic. In other words, the osmotic pressure of the blood plasma is less than that of the interstitial spaces. As a result, water will pass to the interstitial fluid and small molecules and inorganic ions will pass into the blood plasma. The interstitial fluid, then maintaining osmotic equilibrium with the intracellular fluid, gives up water to the cells and the cells are hydrated.

A great deal can be done to prevent the toxemias of pregnancy. Newburgh<sup>1c</sup> has found that impaired kidneys do not produce a highly concentrated urine even though the intake of water is restricted. Dieckmann<sup>5</sup> reported the mean for the maximum specific gravity in normal pregnancy to be 1.022. A patient not ingesting a great deal of fluid and excreting urine having a specific gravity of 1.020 or lower should be considered to have some retention of urinary solids. The presence of renal epithelium in the urinary sediment suggests renal damage.

The treatment of mild toxemia is simple, and progress of the toxemia may be averted. The success of the treatment depends on the cooperation of the patient. Fluids are forced. A urinary output of 2,500 cc. will be ample unless great renal impairment exists. A neutral diet is prescribed. This may be devised from the list of foods prepared by Newburgh.<sup>4</sup> As sodium is a predisposing cause of edema, foods having a low sodium content are chosen, and for the same reason sodium chloride and sodium bicarbonate are eliminated.

Severe nonconvulsive toxemia is treated in a similar manner. The patient should be observed more closely, because of the severity of the symptoms. Hospital

care is of great value. The patient with severe pre-eclampsia may be treated over a long time if large quantities of fluids are given and if the urinary output is maintained large. A neutral diet is necessary, as is acid base equilibrium.

In the case of the convulsive toxemias, fluids cannot be given by mouth; therefore a parenteral route must be chosen. Fluids are more rapidly absorbed when given intravenously, but the subcutaneous method of administration is also valuable. The object is to give large amounts of fluid. Eichelberger and Hastings<sup>6</sup> have demonstrated that hypertonic dextrose solution dehydrates the cells. They found that isotonic dextrose solution would make water available to the cells. Therefore as the cells are already dehydrated and as hypertonic dextrose solution will increase that dehydration, isotonic dextrose solution is given.

The amount of fluid necessary may be determined roughly. Collier and Maddock<sup>7</sup> found that a dehydrated patient had lost 6 per cent of body weight. A convulsive patient weighing 150 pounds (68 Kg.) should have the following needs considered in the first twenty-four hours: water to hydrate the cells, 4,100 cc.; urinary water, 3,000 cc.; vapor water (skin and lungs), 1,000 cc.; total, 8,100 cc. A large estimate must be made for urinary water if the kidneys are to excrete large amounts of retained urinary solids.

TABLE 1.—Distribution of Body Fluid

Extracellular fluid.....	13,600 cc.
Blood plasma .....	
.....	34,000 cc.
Total.....	47,600 cc.

Very little medication is necessary even though convulsions are present. Usually an initial intramuscular injection of soluble phenobarbital will control the convulsions until intravenous treatment is instituted. It has not been necessary to repeat this medication, as the irritability disappears as fluids are given.

Two thousand cc. of 5 per cent dextrose solution may be given intravenously in about two hours. After 1,000 cc. has been given, the administration of 5 per cent dextrose solution by hypodermoclysis is started. A total of 4,000 cc. of the solution is given in about eight hours. The fluid given subcutaneously is absorbed very rapidly. Diuresis is not expected immediately, as available water will first replace that lost by the dehydrated cells. Within twelve hours it is unusual if a patient will not drink water when encouraged. Water is given freely by mouth, but only water. It is usually necessary to give fluids by the parenteral route for several days before a patient will take enough by mouth.

It is generally true that a patient treated in this manner will regain consciousness before renal excretion is reestablished. It seems logical to deduce that all the cells of the body are in such urgent need of water that many processes are suspended. As the cells are hydrated, those processes are resumed. Convulsive patients are not given food until after three days of freedom from convulsions. They are then treated as patients with severe nonconvulsive toxemia.

COMMENT

Starling<sup>8</sup> emphasized first in 1896 and later in 1908 the important relationship between disease and the physiology of body fluids and their electrolytes and colloid osmotic pressures. Since that time his theories have been confined by Darrow and Yannet, Gamble, Peters, Landis, Hastings, Eichelberger and others. Starling noted that the important function of the kidneys is to regulate the amount and composition of the total fluid in the body. If by some change in that function the molecular concentration of the fluid surrounding the cells of the body is altered, it is necessary for the cells to give up or take on water until the osmotic pressure within the cell is equal to that of the extracellular fluid.

Newburgh<sup>10</sup> has demonstrated that a liberal fluid intake is necessary for the proper excretion of urinary solids in persons having impaired renal function. When fetal metabolism increases the normal amount of urinary

TABLE 2.—Summary of Maternal and Infant Mortality for Toxemias of Pregnancy in Cases in Which the Infant Reached a Period of Viability

Date	Antepartum Observation	Cases	Infants	Maternal Mor-tality	Infant Deaths and Still-births	Infant Mor-tality, Per-centage
Nonconvulsive, All Types						
1931-1935 1,000 deliveries; treatment conservative	Yes.....	45	46	0	3	6.5
	Not treated until toxemia was severe	7	8	0	3	37.5

solids, retention may occur as a result of insufficient urinary water. Because of the great reservoir in the interstitial spaces much of the retained material can immediately be removed from the blood plasma so that osmotic equilibrium is maintained. Studies of the blood chemistry do not then reveal a true picture of the retention process.

When retention of urinary solids occurs, the preservation of a normal range in hydrogen ion concentration is a vital necessity. If the diet yields a basic ash, as a diet containing large amounts of fruits, vegetables and milk will, a large part of this excess base must be withdrawn from the blood plasma to prevent alkalosis. A diet rich in cereals and meat will yield an acid ash. The excess acid must be removed or acidosis will result.

The treatment then should be based on removing the retained solids from the organism rather than on neutralizing them, or on treating separate symptoms, such as edema, cerebral manifestations and blood pressure. Large amounts of fluid taken over many days will promote a copious renal output. When the toxemia is of the nonconvulsive type this water may easily be taken by mouth. Most patients will ingest 5,000 cc.

a day with only a little encouragement. In order to avoid the ingestion of any excess acid or base, a neutral diet is given.

In treating eclampsia, control of the convulsions is necessary. This control may be obtained by soluble phenobarbital given intramuscularly. As soon as the convulsions are controlled fluids may be given. The intravenous method is the method of choice at first. Eichelberger and Hastings<sup>9</sup> found that hypertonic dextrose solution produces prompt diuresis but dehydrates the cells. It will not produce a permanent urinary output. There is often a depletion of glycogen in the toxic patient, so at first a large amount of dextrose solution may be utilized. So long as that utilization takes place some water will be liberated to overcome cellular dehydration, but little will be accomplished in removing retained urinary solids. Isotonic dextrose solution, on the other hand, liberates large quantities of water when the sugar is burned.

During the development of toxemia, water is withdrawn from the cells to furnish diluent for excess electrolyte and retained solids. The cells then become concentrated. This increased concentration is in osmotic equilibrium with the extracellular fluid, but the concentration produces a pathologic state within the cells. It is well known that an organism can survive with no food for a long period but that when water is restricted life is limited. The vital part of the organism, the cells, becomes dehydrated under conditions which draw water from the intracellular compartment. This process alters cellular function and endangers life.

De Snoo<sup>9</sup> reported unusually excellent results in preventing eclampsia by the use of a salt-free diet and fluids. He attributed the cause of the convulsion to salt rather than to a physicochemical change in the relationship between the blood plasma, the interstitial fluid and the intracellular fluid. Failure to consider the reaction of the residue of the diet will account for the rare failure of his treatment.

The milk diet has gradually been abandoned by many obstetricians because it apparently instituted convulsions. Milk yields an alkaline ash but, if with each glass of milk one and one-half slices of salt-free bread are ingested, an ideal neutral diet is provided. With this diet many patients may be treated at home without the help of an expert dietitian.

The dehydration therapy of Arnold and Fay has been used successfully by the originators. Over a long time, serious damage to tissues must result unless sufficient water is given to allow the kidneys to excrete all the urinary solids. However, when a dry diet is used as they specify, it must of necessity yield an acid ash. This diet would be of great value for a patient having gross edema, as much of the edema fluid would be liberated to provide sodium ions to maintain a normal hydrogen ion concentration. For patients having no edema and other signs of toxemia, the treatment is dangerous.

The action of magnesium sulfate is not known. Stander<sup>10</sup> found in experimental work that magnesium sulfate produced moderate necrosis in the central part of the lobule of the liver and moderate degeneration in the convoluted tubules of the kidneys. As serious damage to the liver and kidneys may result from the

toxemia alone, it seems unwise to use a drug which may increase the damage. It is possible that magnesium sulfate may be most valuable by furnishing the acid  $\text{SO}_4$  ion.

Most low protein salt-free diets are unsuccessful because the ash is strongly basic. If the diet was designed to yield a neutral ash it would be satisfactory.

Recently great emphasis has been placed on plasma proteins. Darrow and Yannet found that electrolyte accounted for about 90 per cent of the osmotic pressure exerted by body fluids. They also found that when electrolyte was increased the plasma proteins decreased. When the extracellular fluid is made hypertonic by retained urinary solids and electrolyte, water is drawn from the cells to maintain osmotic equilibrium between the intracellular and the extracellular fluid. The extracellular fluid is diluted by the additional water and the plasma proteins will be relatively decreased. It is not easy to increase the plasma proteins by diet, but they may be increased by removing excess electrolyte, by the ingestion of large amounts of water.

By following the treatment outlined it is possible to treat patients having considerable tissue damage, provided enough water is ingested to allow impaired kidneys to excrete retained urinary solids. It must constantly be borne in mind that the cells will be dehydrated to some extent when edema exists. Therefore a successful treatment should point first toward hydrating the cells and second toward promoting urinary excretion. The fact that coma disappears before urinary excretion becomes normal when fluids are given freely suggests that cellular dehydration has an important role in the pathologic process of the toxemias of pregnancy.

This treatment will control the development of severe toxemia, making it unnecessary to induce labor in a seriously toxic patient until after the toxemia is under control. The maternal risk is greatly decreased, and in addition the fetal mortality is lessened. The modern tendency to induce labor as toxemia becomes more severe leads to a low maternal mortality, but many babies are lost as a result of fetal toxemia and prematurity. A successful method of treating the toxemias of pregnancy should be productive of a low fetal mortality as well as a low maternal mortality.

The result of treating the toxemias in 2,000 consecutive deliveries is presented in table 2. The toxic patients were divided into two groups. The group seen for the first time with severe toxemia was eliminated as having had no antepartum care. In most instances fetal heart tones were not heard when the patient was admitted; therefore treatment had no bearing on the fetal mortality.

In the group receiving antepartum care an interesting comparison is possible. One thousand patients were delivered between Aug. 1, 1931, and June 1, 1935. Forty-five had a nonconvulsive toxemia. The fetal mortality was 6.5 per cent. Two patients had eclampsia. Only one convulsion was recorded for each patient. The treatment in this group was conservative. Fluids were given in moderate amounts, and the diet was low in protein and salt. No attention was paid to the reaction of the diet, and it consequently yielded a basic ash. Labor was induced if the toxemia became more severe.

A second group of 1,000 patients was delivered between June 1, 1935, and March 20, 1938. Fifty-three had a nonconvulsive toxemia. There were no convulsive patients. The treatment was as outlined in

this paper. Fluids were forced, and a neutral diet low in sodium was given. The fifty-three mothers were delivered of fifty-four babies. One baby, a fetal monstrosity, was lost, so that the fetal mortality was 1.8 per cent.

#### SUMMARY

1. The toxemias of pregnancy occur in women with some previous impairment of renal function. This impairment leads to a gradual retention of urinary waste and electrolyte.

2. Retention of urinary solids leads to dehydration of all the cells of the body and the fetus. Dehydration alters the function of the cells and accounts for metabolic changes in the various organs of the body.

3. Retention of electrolyte is responsible for the different types of toxemias. A diet yielding an alkaline ash leads to retention of alkaline ions and the development of cellular dehydration in the presence of edema. A diet high in acid ash leads to retention of acid ions with general dehydration of all cells.

4. The toxemias may be prevented by the ingestion of large quantities of fluid and a neutral diet low in sodium if treated early, or they may be controlled at any time if treated before severe cellular damage has resulted.

5. The infant mortality for the toxemias of pregnancy can be lowered.

410 Central Avenue.

#### ABSTRACT OF DISCUSSION

DR. P. J. CARTER, New Orleans: Dr. McPhail's paper is in keeping with the present day treatment of the toxemias of pregnancy. I agree that urinary solids should never be allowed to be retained on account of the accumulation of urinary waste and electrolyte in the blood plasma, as a result of impaired renal function. An attempt to secure a neutral ash is important, for if renal function is hampered a disturbance in water balance may occur with a resulting toxemia. The mechanism by which water is displaced or added to in a toxic individual and the reaction of the tissues and cells to such a toxemia are excellently outlined in Dr. McPhail's paper. The effect on the kidney shows the most striking abnormalities in toxemia; it is believed that toxemia will not develop when no impairment of renal function exists. The adage "dehydrate in edema" has well stood the test, and the proper use of the tonic solutions of dextrose has been our greatest accomplishment in lessening the maternal and fetal mortality in the toxemia of pregnancy. In our present knowledge of cell activity whereby little or no edema occurs when water becomes bound up in the cell protoplasm, as against visible edema when the fluid accumulates in the intracellular spaces, we have an important factor influencing water balance. I cannot agree with Dr. McPhail in giving 2,000 cc. of 5 per cent dextrose solution intravenously in about two hours, with a total of about 4,000 cc. in about eight hours. This seems to me an excessive amount of water to give a patient in eclampsia, in which the heart action has been disturbed and disabled, and this amount would tend to cripple its action still further. My observations through the Charity Hospital at New Orleans, where we have an abundance of material, have been that eclamptic patients fare better with a lesser amount of concentrated solution at longer intervals; namely, 500 cc. of a 20 per cent solution intravenously every six hours or even in a greater concentration in the individual case. In the toxemias of pregnancy we are still treating the symptoms of a disease of little known origin, but which reveals to us a disturbed water balance in which an excessive intake or output results in the accumulation in the intracellular spaces of water producing edema, or accumulating in the cells with little or no edema. In summing up, the salt element and its concomitant reactions with retention and storage of chlorides play a most important part in the development of pregnancy toxemia. One cannot begin to attain a proper water balance and a proper ratio in osmotic pressure, which are essential in the treatment

of this disease, when one loads the overburdened tissues and cells with additional water and excess of electrolyte.

DR. LYLE G. McNEILE, Los Angeles: I congratulate Dr. McPhail in presenting a new concept of the etiology of the toxemias of pregnancy and the development of a treatment based on a new concept. Any theory, however, must establish beyond question the premises on which it is based. It appears to me that in order for Dr. McPhail to establish his case he must either assume or prove certain facts. First he must prove that there is renal impairment in all cases of toxemia. Delicate clearance tests of kidney function in the toxemias have frequently failed to disclose such impairment. Secondly he must demonstrate that the degree of renal impairment must be sufficient to cause a retention of electrolytes (sodium, potassium, chloride and the like as well as urinary solids). In the early stages of eclampsia there almost always is no impairment of the concentrating power or of the ability of the kidneys to excrete electrolytes. The concentration of the urine during the phase of acute oliguria is usually over 1.030. Page, in my clinic, has made numerous Addis tests of concentrating power in selected cases of severe eclamptogenic toxemias and has failed to obtain specific gravities of less than 1.026 on any of them after from eighteen to twenty-four hours of dehydration. The work of Newburgh and others quoted by Dr. McPhail refers only to the amount of water required to excrete urinary solids when there is a known impairment of concentrating powers of the kidney. Dieckmann, Killian and Stander, moreover, have found that the concentration of electrolytes in the blood of eclamptic patients is within the normal range. The author answers this in his paper by stating that blood chemical studies do not always reveal "a true picture of the retention process." As affecting certain phases this may be true, but in the matter under discussion it is hardly true, for the electrolytes are freely permeable through capillaries and are in constant equilibrium between the blood and extracellular fluids. Thirdly the proponent of this theory must show that such a retention of electrolytes would lead to a "cell dehydration" without producing general dehydration. Darrow and Yannet state that the loss of electrolytes produces the symptoms and signs of dehydration but that an increase of extracellular electrolytes experimentally leads only to the symptom of extreme thirst. I have never noted such pathologic thirst as a symptom of toxemia. Is it true that the blood in eclampsia becomes hypertonic? Harden and his associates, Seitz, and the authors of the first paper on our program seem to have demonstrated that the blood may become hypotonic through loss of albumin in the urine. This would lead to cell hydration rather than cell dehydration. Most important, a proponent of this theory must show that cell dehydration would lead to a suspension of cell function or to any of the symptoms of eclampsia.

DR. FRANCIS L. MCPHAIL, Great Falls, Mont.: Darrow and Yannet noted dry mucous membranes and increased thirst in animals after increasing the extracellular electrolyte. In experiments a large amount of salt was injected into small animals. When a retention process develops in pregnancy it develops slowly and the extracellular electrolyte is probably increased to a lesser degree. Nevertheless the mucous membranes appear dry in many toxic patients. If 500 cc. of 20 per cent solution of dextrose is given, very little water will pass into the cells. While glycogen depletion is present in the toxemic state, a concentrated solution of dextrose may be utilized, but as glycogen is replaced in the tissues only a small amount of dextrose is oxidized and little water is liberated to hydrate the cells. A method of treatment has been presented which has worked well in the prevention and treatment of eclampsia and in the treatment of severe nonconvulsive toxemias. It does not depend on polypharmacy. Adequate renal excretion and restoration of function have resulted. The value of the treatment may be determined after a fair trial.

**Duration of Life in Sixteenth Century.**—In the sixteenth century the average duration of life was eighteen years. Fully one-half the population of every country died under the age of twelve, and 60 per cent of those died before their fifth year.—Hurd-Mead, Kate Campbell: *A History of Women in Medicine*, Haddam, Conn., the Haddam Press, 1938.

## RELATION BETWEEN BLOOD PLASMA PROTEINS AND TOXEMIAS OF PREGNANCY

A PRELIMINARY REPORT

EVA F. DODGE, M.D.

MONTGOMERY, ALA.  
AND

THOMAS T. FROST, M.D.

WINSTON-SALEM, N. C.

Diets for pregnant women are not modern, though their use in the past was more empiric than scientific. The angel in Biblical times gave the father of Samson instructions before his birth, saying "She may not eat of anything that cometh from the vine, neither let her drink wine or strong drink nor eat any unclean things" (Judges 13:14). Since then each generation has added or subtracted, restricted or insisted, on a variety of foods. The textbooks of the middle nineteenth century have practically no antepartum advice and only mention that an adequate diet should be prescribed for convulsions without saying what constitutes an adequate diet.<sup>1</sup> Even as late as 1928 De Lee,<sup>2</sup> in his antepartum instructions concerning diet, did not advocate a balanced diet. He advised that the patient "omit meats and broths and limit eggs and fish." Curtis,<sup>3</sup> with two full pages on diet, said "Meat is to be taken moderately." This is an advance toward balancing the diet. Beck,<sup>4</sup> however, hewed to the conventional diet of the past—the decreasing of proteins during the latter part of pregnancy and the restricting of proteins in the case of toxemia, the animal proteins being replaced with vegetable proteins.

Several years ago it became evident to one of us that certain patients in the antepartum clinic of the City Memorial Hospital of Winston-Salem, N. C., who had edema or high blood pressure seemed to improve clinically even though they continued to eat meats when instructed to abstain. As this was before an increase of protein in the diet was beginning to be advocated, it was thought best to stress a salt-free and porkless diet, omitting the restriction of other proteins but urging, as before, that more milk be taken. Many patients volunteered the information that they ate beef and eggs, and these were not restricted in amount. With this diet there were no cases of eclampsia in the clinic in four years, though previously there had been several cases each year.

During a conference with Strauss in Boston in 1936 we mentioned the fact that, while we did not advocate the use of proteins during the latter part of pregnancy or in cases of toxemia, we did not restrict them and our patients were consuming varying amounts with no apparent harm. Strauss at this time was studying the effect of very high protein diets on toxemia, diets with 260 Gm. of protein daily, in the form of milk, lean meats and egg whites. His patients lost weight, their blood pressure fell, the subjective symptoms abated and

Mr. Walter Mickle cooperated in the laboratory determinations. Read before the Section on Obstetrics and Gynecology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

1. Meigs, Charles D.: *Treatise on Obstetrics: The Science and Art*, ed. 2, Philadelphia, Lea & Blanchard, 1852.

in some cases the albuminuria was decreased. These had been the effects, to a lesser degree, with some of our patients when they had taken protein against our instructions. We planned to give some of our clinic patients an increased protein intake, as a routine, to see how they would react. Because of the low economic status of our patients and our lack of hospital beds for experimental work we arbitrarily decided on six whole eggs a day in addition to the 1 or 2 quarts of skim milk and the legumes which they might have. They were told to eat whatever meat they had, aside from salt pork. Knowing that an increase of protein was against previous training, we did not feel it wise to omit the magnesium sulfate when indicated and insisted that they use a salt-free diet. Most of the patients reported that they felt so much better and a few of the toxemias improved so dramatically that it became a routine to have the patients add six or eight whole eggs to their daily diet. One of the first patients given this diet was a Negro girl aged 14, seen in one of our rural antepartum clinics. She was eight months pregnant, had a blood pressure of 190 systolic, 110 diastolic, a 2 plus reaction for albumin, and edema, with headache and dizziness, and appeared very stupid. She was put on the old routine of a low protein diet, with from 2 to 3 quarts of skim milk daily, rest in bed and magnesium sulfate. At the next clinic, two weeks later, she had gained 10 pounds (4 Kg.), appeared more stupid and had a blood pressure of 200/115. Both the mother and the nurse who had seen her during the past two weeks assured us that she had followed instructions. We added from eight to ten whole eggs to the milk, thus giving her around 90 Gm. of protein a day. The family lived in the country and had enough eggs for her. When seen two weeks later she had lost 10 pounds, was very clear mentally and had a blood pressure of 140/90 and no albuminuria. She was delivered spontaneously before her next clinic visit, without any evidence of toxemia appearing during or after labor.

It was about this time that Harden's<sup>5</sup> monograph was brought to our attention. In his cases he attempted to maintain a positive balance of nitrogen in order to supply the fetal requirements without depleting the maternal proteins. He calculated the amount of protein required in the cases of toxemia by adding to the minimum amount required for maintenance 50 Gm., the amount of protein metabolized, as evidenced by the end products in the urine and the estimated requirements of a 2 kilogram fetus. His patients averaged from 75 to 80 Gm. of protein daily. Though we had chosen our amounts arbitrarily, we found that we had been giving approximately the same amounts as Harden. In a four year series he<sup>6</sup> found that none of the 522 patients given his protein stabilization diet had had convulsions, while the frequency of convulsions in referred cases in the locality remained the same. Our experience has been similar, as will be shown.

Our empirically chosen amounts of protein and the calculated amounts of Harden were considerably less than the amounts given by Strauss. While our clinic patients were having no eclampsia, some were having toxemia, though it was milder in those who were able to obtain the milk and eggs. Were the toxemias of our patients who subsisted on turnip greens, sweet pota-

toes and corn bread, with occasionally fresh fish and pork, due to a lack of protein or to an improperly balanced diet, which needed a positive balance of other nutritive factors required by the fetus? We determined to estimate the blood plasma proteins of a series of patients who were receiving the type of diet which they would have had if they had not been pregnant or had had no instructions in diet to see whether there was a significant change in plasma proteins. These patients were instructed to eat and live as they had before they knew that they were pregnant. As we had previously been urging them to increase the proteins by adding milk, eggs and cheese to the diet and to cut down the salt intake, we did not begin to collect the specimens of blood until after they had been on their new diet for at least a week. They were told to take no magnesium sulfate and to eat the same amount of salt they usually did, as well as to prepare the food with seasoning meat.

The plasma proteins of the blood of thirty-four non-pregnant women of the same social status from the clinic were used as controls.

Chart 1.—Plasma albumin and globulin concentrations for thirty-four nonpregnant women of the same economic status as the pregnant women, for the pregnant women as a group and for the pregnant women by trimester. In the charts each square and circle represents one determination, and the horizontal lines represent the average values for each group. (See text for probable error of means.)

Persons who have worked with clinic patients realize that they cannot be controlled like guinea pigs in cages. However, in choosing the patients for this study we tried to make sure that those classified as having a normal pregnancy or receiving a regular diet were not getting a high protein intake. Some of the patients in this group should probably be included in the high protein group, as we had a feeling that they were eating more protein than they would admit. This is easy to understand, because, having been on an adequate protein diet previously, they did not feel as well with a restricted protein intake. As a result of this our figures may be somewhat higher than they ought to be, particularly for the third trimester.

The albumin and globulin were determined by the method of Bowman. It was thought well to divide the pregnant patients according to the three trimesters and to group together those who we were certain were on a high protein diet and those who had toxemia. The patients with toxemia all had a blood pressure of 145/100 or higher and were known to have had a nor-

6. Harden, Boyd: Clinical Management of Pre-Eclampsia and Eclampsia, Pennsylvania M. J. 40: 835-837 (July) 1931.

mal blood pressure early in pregnancy. Ninety-seven determinations were made for the pregnant women. Three cases occurred in the first trimester; thirty in the second and sixty-four in the third. Twelve of the patients were on a high protein diet, and forty-two were on the regular diet. Eight had definite toxemia.

Chart 2.—Plasma albumin and globulin concentrations for the pregnant women in relation to (1) toxic condition, (2) nontoxic condition, (3) high protein diet and (4) regular diet.

The normal values, according to the literature, are from 4.5 to 5.5 Gm. per hundred cubic centimeters of plasma for albumin and from 1.5 to 3 Gm. per hundred cubic centimeters of plasma for globulin.

The class values for the various groups were scaled to 0.15 divisions; for example, all values for globulin in the class 1.6 Gm. were 1.52 Gm. or more and less than 1.67 Gm.

The average, or mean, for the nonpregnant women was  $4.90 \pm 0.06$  Gm. for the albumin and  $1.88 \pm 0.06$  Gm. for the globulin, showing low values but within the normal range. Most of these patients were of the low economic group, who eat only small amounts of meat and milk and few eggs.

The pregnant women as a whole showed a lower mean value than the nonpregnant women, the mean for albumin being  $4.27 \pm 0.04$  Gm. and for globulin  $2.01 \pm 0.04$  Gm. The mean values for albumin for the first trimester,  $4.70 \pm 0.18$  Gm., were higher than those for the pregnant women as a group but lower than the mean for the nonpregnant women. The number of women in the first trimester was very small because most clinic patients do not come to the clinic before the fourth month. The mean value for globulin for this group was lower than that for all the pregnant women, being  $1.5 \pm 0.14$  Gm. There was very little difference in the mean values for albumin for the second and third trimesters, but the values for both were lower than for the first trimester or the nonpregnant women, being  $4.18 \pm 0.06$  Gm. and  $4.30 \pm 0.05$  Gm., respectively. The mean values for globulin for the second and third trimesters were  $2.11 \pm 0.06$  Gm. and  $1.99 \pm 0.05$  Gm., respectively.

The values for patients with toxemia showed a definite lowering of the albumin to  $3.87 \pm 0.03$  Gm. but a rise in globulin to  $2.07 \pm 0.09$  Gm. The change in albumin is in agreement with the experience of Strauss and others. The rise in globulin is a new observation

and should be verified. It may be in the nature of a compensatory rise. For the patients receiving a high protein diet, the values were very close to those for the controls; namely,  $4.90 \pm 0.09$  Gm. for albumin and  $1.76 \pm 0.12$  Gm. for globulin, the globulin average being slightly lower than that for the control patients. None of the patients receiving a high protein diet showed any evidence of toxemia, and subjectively they felt very well. Their urine and their blood pressure remained normal. The values for the patients receiving the regular diet were lower than those for the nonpregnant women, being  $4.04 \pm 0.04$  Gm. for albumin and  $2.25 \pm 0.05$  Gm. for globulin.

Chart 3 shows four representative cases. The first two patients had normal blood pressure and weight gain with no toxic symptoms:

CASE 1.—D. E., a Negro primipara aged 17, seven months pregnant, was told to forget her pregnancy and to eat as she pleased. This was her first pregnancy, and she had had no dietary instructions previously. The plasma albumin content dropped gradually from 4.13 to 3.84 Gm. as the globulin rose from 2.12 to 2.28 Gm.

CASE 2.—E. H., a Negro tertipara aged 21, eight months pregnant, was told to follow her regular diet but after two weeks admitted that she had been adding eggs and milk because they made her feel better. We insisted that she refrain from taking the proteins, and on the subsequent two visits she assured us that she was eating as she did when not pregnant.

The next two cases illustrate the effect of the change in diet:

CASE 3.—R. S., a Negro sextipara aged 32, six months pregnant, was changed from her regular diet to one high in protein, containing from 70 to 80 Gm. a day. The albumin rose from 3.98 to 5.07 Gm. and the globulin fell from 2.79

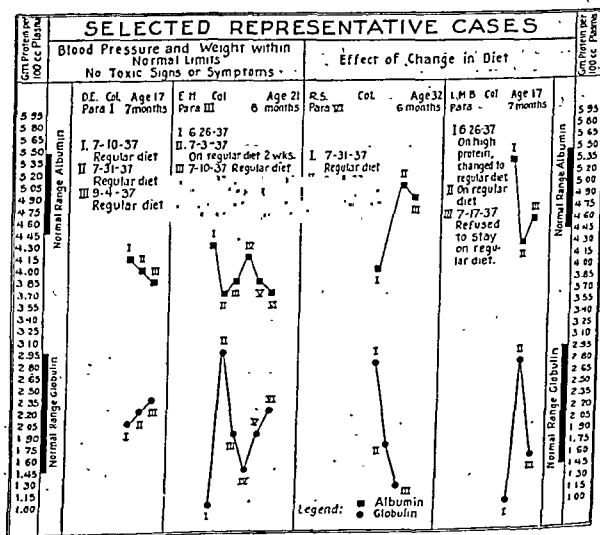

Chart 3.—Plasma albumin and globulin concentrations for four patients, showing the effect of regular diets and a change in diet.

to 1.71 Gm. She had had no complaints or symptoms previous to the change in diet. The next month there was a drop in the albumin and globulin.

CASE 4.—L. M. B., a Negro primipara aged 17, seven months pregnant, had been receiving a high protein diet for two or three weeks and was told to return to her old way of eating. One week later the albumin had fallen from 5.30 to 4.23 Gm. and the globulin had risen from 0.83 to 2.37 Gm. She refused to remain on her old diet and had been increasing the amount of milk and eggs. At this time the albumin had risen to 4.67 Gm. and the globulin had fallen to 1.65 Gm.

As has previously been stated, the rise in the globulin with the lowering of the albumin in the plasma is apparently a new observation and should be verified.

## COMMENT

Rosenstein<sup>7</sup> more than sixty years ago advanced the theory that cerebral edema caused eclampsia and that edema was due to the effusion of serum from the "too watery" blood into the cerebral tissues. Thirteen years later Charpentier<sup>8</sup> agreed with others that a diminished amount of albumin in the blood was a predisposing cause in the production of eclampsia. Wieloch<sup>9</sup> in 1925 reported the universal occurrence of water retention in his cases of toxemia of pregnancy. Bingham<sup>10</sup> found that toxemia developed in his patients only with excessive gain in weight. The cause of edema in toxemia has been attributed to many things: excessive production of the pituitary antidiuretic hormone,<sup>11</sup> primary kidney disease,<sup>12</sup> instability of the plasma colloids,<sup>13</sup> pressure on the ureter of the enlarged uterus<sup>14</sup> and excess of sodium chloride.<sup>15</sup> In 1937 Strauss<sup>16</sup> observed that patients with hypoproteinemia had a significant gain in weight, with visible edema, rises in blood pressure and in a few cases albuminuria, when sodium was administered as chloride or bicarbonate.

Strauss<sup>17</sup> found that in cases of toxemia with or without convulsions the plasma albumin is lower than that of pregnant women receiving an average diet. The average level of the globulin in his cases was not lower than that of pregnant women receiving an average or low protein diet. The average level of plasma albumin for all our pregnant women was higher than that of his patients. Those of our patients who had signs of toxemia had an average level higher than that of Strauss's patients. The average level of globulin in our cases was lower than in Strauss's cases except in those of toxemia, in which it was slightly higher.

As yet there does not seem to be a clearly defined cause for the lowering of the plasma proteins during pregnancy. It has long been recognized that the fetus is a parasite, drawing from the maternal organism the necessary nourishment for its development and growth regardless of the depletion of the mother's tissues. It is known that calcium will be removed from the body when the blood does not contain a sufficient amount to supply the needs of the fetus. Proteins are essential for growth and repair of body tissue in the adult and certainly are required in considerable amounts by the fetus and its membranes. It would seem necessary for the mother to supply by her diet sufficient proteins to maintain her own growth and repair and supply the needs of the fetus if she is not to deplete her own tissues. That there is a definite decrease in the plasma protein can be seen by our figures, which corroborate those of other authors. As has already been noted, there is considerable variation in the amount of protein which is considered to be adequate in normal pregnancy and in toxemias. The League of Nations Technical

Commission of the Health Committee on Nutrition<sup>18</sup> recommended for normal pregnant women from 1.5 to 2 Gm. of protein daily for each kilogram of body weight, which would mean from 70 to 130 Gm. a day for the woman of 150 pounds (68 Kg.); this is a little higher than the intake advised by Harden<sup>5</sup> in cases of toxemia but considerably less than that used by Strauss<sup>17</sup> in his cases. The revised report of this committee<sup>19</sup> stated, in listing the protein requirements of pregnant women, that "some animal protein is essential and in the growing period should form a large proportion of the total protein." The daily amount of protein after the fourth month of pregnancy recommended in this report is 1.5 Gm. per kilogram of body weight.

## SUMMARY

1. In pregnant women the blood plasma albumin is decreased below the level found in nonpregnant women.
2. Toxemias of pregnancy uncomplicated by organic disease are associated with a significant decrease of plasma albumin and a questionable increase of the globulin. The increase of the globulin needs further investigation.
3. Pregnancy without signs of toxemia and a diet deficient in protein cause a decrease in plasma albumin.
4. An increased intake of protein in cases of mild toxemia causes an alleviation of objective and subjective symptoms and signs and is well tolerated by the patient.

## ABSTRACT OF DISCUSSION

DR. THOMAS ADDIS, San Francisco: The authors of the paper are conservative when they say that they do not think a "clearly defined cause for the lowering of the plasma proteins in pregnancy" has been demonstrated. Their own observations as well as other clinical and experimental data show that the principal and necessary cause is a protein intake that is too low relatively to the greatly increased need for protein during pregnancy. My associates and I have completed experiments in which we compared the total body protein and organ protein of two groups of rats of identical original body weights, one a control group of female rats and the other a group in late pregnancy. We found that in all parts of the body the concentration of protein was less in the pregnant than in the control group and that the greatest change occurred in the blood serum, where the protein content fell from 6.7 per cent to 5.4 per cent. The cause of this change is given by the observation that the pregnant group were obliged to allocate 10 per cent of all the protein in their bodies for the construction of the embryos and uterus and had to use in addition 5 per cent of their total protein for new construction that the pregnancy made necessary. The mothers did their best to meet this requirement by eating more food. But the protein concentration was too low. Even though they ate 50 per cent more than the controls they could not get enough protein. Their gastrointestinal capacity was the limiting factor. As a consequence, they fell into a protein deficit, and the debt was paid at the expense of the mothers for the benefit of the babies. Drs. Dodge and Frost will agree that the need for more protein in the diet continues beyond pregnancy and throughout lactation. We are finding that in rats a diet that is entirely adequate for growth fails to maintain the usual protein content of the mothers' organs and tissues during lactation. The practical importance of these observations of Drs. Dodge and Frost is unquestioned. They give direct evidence that diets sufficient under ordinary conditions for maintenance are grossly inadequate in protein concentration during pregnancy. If we are to exclude the gastrointestinal tract as a limiting factor, it is not enough to give plenty of all sorts of food. We must see that pregnant and lactating women are given food with a high proportion of meat, fish, milk and eggs. From an economic point

of view this may sometimes be difficult, but that it is a strict requirement from the point of view of physiology and of medicine there can be no doubt.

DR. BOYD HARDEN, Burlington, N. C.: I wish to make one point concerning nitrogen deficits in the toxemias of pregnancy. The discussion is based on the premise that there is a physiologic optimum beyond which the administration of protein may accomplish no benefit; there is a pathologic minimum below

### Study of Nineteen Preeclamptic and Nineteen Eclamptic Patients

#### PREECLAMPTIC PATIENTS

Average Height	Average Weight	Average Age	Average Intake in Grams		
			Protein	Fat	Carbohydrate
155.49 cm.	80.4 Kg.	33 years	82	61.1	218
On the Du Bois Chart:					
155.49 cm. meets 80.4 Kg. at 1.8 square meters.					
At 33 years of age the female requires 36.2 calories per square meter of surface area per hour.					
1.8 square meters $\times$ 36.2 calories $\times$ 24 hrs. = 1,563.84.					
Dietary values:					
Protein .....	82.0 Gm.	$\times$ 4 calories per gram			328.00 calories
Fat .....	61.1 Gm.	$\times$ 9 calories per gram			549.90 calories
Carbohydrate .....	218.0 Gm.	$\times$ 4 calories per gram			872.00 calories
Administered in diet.....					1,749.90 calories

Urine:					
Average total nitrogen.....	7.60	Protein equivalent..	47.50 Gm.		
Average nonprotein nitrogen	6.68	Protein equivalent..	41.75 Gm.		
		Protein loss.....	5.75 Gm.		

Feces:					
Average total nitrogen.....	2.20	Protein equivalent..	13.75 Gm.		
Analysis:					
Protein administered and consumed.....	82.00 Gm.				
Protein metabolized and lost.....	61.25 Gm.				
Protein stored .....	20.75 Gm.				

This protein storage appears in the presence of a starvation level of excretory products of nitrogen in urine. The actual level of excretory products of nitrogenous metabolism was 0.52 Gm. per kilogram of body weight.

#### ECLAMPTIC PATIENTS

Average Height	Average Weight	Average Age	Average Intake in Grams		
			Protein	Fat	Carbohydrate
154.1 cm.	80 Kg.	26.3 years	69.4	61	209
On the Du Bois Chart:					
154.1 cm. meets 80 Kg. at 1.8 square meters.					
At 26.3 years of age the female requires 36.6 calories per square meter of surface area per hour.					
1.8 square meters $\times$ 36.6 calories $\times$ 24 hours = 1581.12 calories as the basic caloric requirement of the mother.					
Dietary values:					
Protein .....	69.4 Gm.	$\times$ 4 calories per gram			277.60 calories
Fat .....	61.0 Gm.	$\times$ 9 calories per gram			549.00 calories
Carbohydrate .....	209.0 Gm.	$\times$ 4 calories per gram			836.00 calories
Administered and consumed in diet.....					1,662.60 calories

Urine:					
Average total nitrogen.....	7.42	Protein equivalent..	46.37 Gm.		
Average nonprotein nitrogen	6.08	Protein equivalent..	38.00 Gm.		
		Protein loss.....	8.37 Gm.		

Feces:

Analysis:					
Proteins administered and consumed.....	69.4 Gm.				
Proteins metabolized and lost.....	67.6 Gm.				
Protein stored .....	1.8 Gm.				

This protein storage appears in the presence of a starvation level of excretory products of nitrogen in urine. The actual level of excretory products of nitrogenous metabolism was 0.425 Gm. per kilogram of body weight.

which the restriction of this vital constitutional element must result in manifestations of deficit. Further, in severe hepatic disease the selection of proteins essential in growth and development is necessary to the pattern needs of the fetus and the storage demands of the maternal host. This study represents a period of seven years during which 739 consecutive admissions with late gestational toxemia and eclampsia were studied under a regimen designated as protein stabilization. Nineteen patients with typical manifestations in preeclampsia and a like number with eclampsia have been selected for this discussion. During the seven years, no patient with well defined preeclampsia developed eclampsia under the regimen of protein stabilization, while the incidence of eclampsia in the community remained the same

that it was before the institution of this regimen. The application of the usual methods of antepartum care and the compensation of nitrogen deficits have proved life saving in our hands in preeclampsia and eclampsia.

DR. EVA F. DODGE, Montgomery, Ala.: We felt that we should have a larger number of determinations before drawing final conclusions. The few patients who were given the increased protein diet, particularly the eggs, milk and cheese which we found to be within the reach of our rural clinic patients despite their low economic status, were apparently helped by this diet. A pregnant girl of 13 years who was not included in the case reports had a high blood pressure without any other marked toxic symptoms. The blood pressure did not come down with an adequate protein diet. Labor was induced because of the continued high blood pressure. As her blood pressure was about 200 systolic and 110 diastolic six months after delivery we felt that it was not a protein deficiency which was responsible for the high blood pressure. We feel that the whole egg may have something to do with this problem and are now advocating the use of the whole egg instead of just the whites of the eggs. We realize that during lactation the mother needs protein, but our work was entirely with the antepartum group and we did not go into the postpartum problem.

### RADIOSENSITIVITY OF MALIGNANT NEOPLASMS OF THE UTERINE CERVIX

HARRY H. BOWING, M.D.

AND

ROBERT E. FRICKE, M.D.

ROCHESTER, MINN.

Carcinoma of the uterine cervix is radiosensitive. Radiosensitivity means sensitive to radiant energy; specifically it is used to describe certain tumors that are susceptible of being injured or destroyed by radium and roentgen rays. This fact was soon learned by the early workers in the field of radium therapeutics. The disease was among the first malignant tumors observed to be amenable to the rays of radium.

The radiosensitivity of the lesion under consideration is relative, since the degree of injurability or destroyability is dependent on many factors. Apparently some of these factors can be evaluated, at least in a measure or in a limited degree. Ewing said: "The general condition of the patient determines the result of radiation, regardless of nearly all other factors. In fresh subjects in good general health, without anemia or cachexia, the results of radiation are usually prompt and definite, whereas in anemic and cachectic subjects with poor circulation, tumors may fail entirely to respond." Some of these factors can be recognized grossly while others are recognized microscopically. The former lend themselves rather well to recognition and discussion while the latter may be studied only by examination of material which is removed at operation or for biopsy, and by postmortem examination of specimens by skilled pathologists. As a rule, the supply of tissue for microscopic study is very limited, especially when one considers that the response to treatment requires days or weeks and that repeated removal of tissue is necessary. During a course of treatment the removal of representative tissue from time to time for microscopic study and for the evaluation of the results of treatment is considered dangerous or inadvisable.

From the Section on Therapeutic Radiology, the Mayo Clinic. Read before the Section on Radiology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

The capacity of a given malignant lesion of the cervix to respond to irradiation can be determined by frequent observations during the course of treatment, and the duration of this response can be in a measure determined by the number of three year or five year cures in a group of cases. The data presented in this paper were obtained from our daily experience and from the three year results obtained in a group of 1,491 cases in which treatment was given in the years 1915 to 1929 inclusive. As a rule the diagnosis can be made from the chief complaint, history, bimanual pelvic examination and inspection of the vaginal cavity, preferably with the patient in the knee-chest position. The removal of small bits of tissue for microscopic study is of value in confirming the clinical diagnosis and in determining the grade of malignancy. Material for biopsy can be obtained with but little, if any, risk. The diagnosis was confirmed by histologic examination in 947 cases; 872 of the 947 patients were traced after they left the clinic; 372, or 42.7 per cent of these patients, lived three or more years after the treatment. In the entire series of 1,371 traced patients 473, or 34.5 per cent, lived three or more years after the treatment. In the early years covered by this study a biopsy was an elective procedure, but at the present time it is performed as a matter of routine. The routine performance of biopsy has advanced our knowledge of this dreaded disease. Malignant neoplasms of the uterine cervix consist chiefly of squamous cell epitheliomas, which have a dominant tendency toward the higher grades of malignancy. The remaining small group is made up of adenocarcinomas and a few mixed lesions which contain both of these malignant cellular elements. In the majority of the cases an extensive primary lesion is associated with an inflammatory or degenerative process and the therapeutic management<sup>1</sup> requires special consideration.

From the standpoint of radium therapy it is important to classify the lesions according to the extent of the primary and secondary involvement. The following classification has proved satisfactory: Stage 1 indicates that the primary lesion is limited to the uterine cervix, stage 2 indicates that the primary lesion has extended beyond the original site but the uterus is movable, stage 3 indicates that the primary lesion has extended further than in stage 2 and that the uterus is definitely fixed, stage 4 indicates a "frozen pelvis" with extensive pelvic involvement and the probable presence of local and distant metastasis. The term "modified" is used to describe the stage of involvement in cases in which some type of therapeutic procedure

had been employed before the patients came to the Section on Radium Therapy. Modified stage 1 denotes that the active lesion is rather small, while modified stage 4 denotes that a "frozen pelvis" is present.

The radium technic employed at the clinic in the treatment of carcinoma of the uterine cervix may be defined as an intensive, multiple or broken-dose method. This procedure is orderly, flexible and effective. The radium therapist should have at his disposal an assortment of applicators such as universal tubes, various needles and gold (radon) seeds. The treatment factors, that is, the amount of radium, the filtration and the distance, as a rule should remain constant, while the time of application and the interval between applications should be varied to meet the needs of the patient. Nearly all patients are placed in the knee-chest position in order to permit careful inspection and the introduction of applicators without trauma

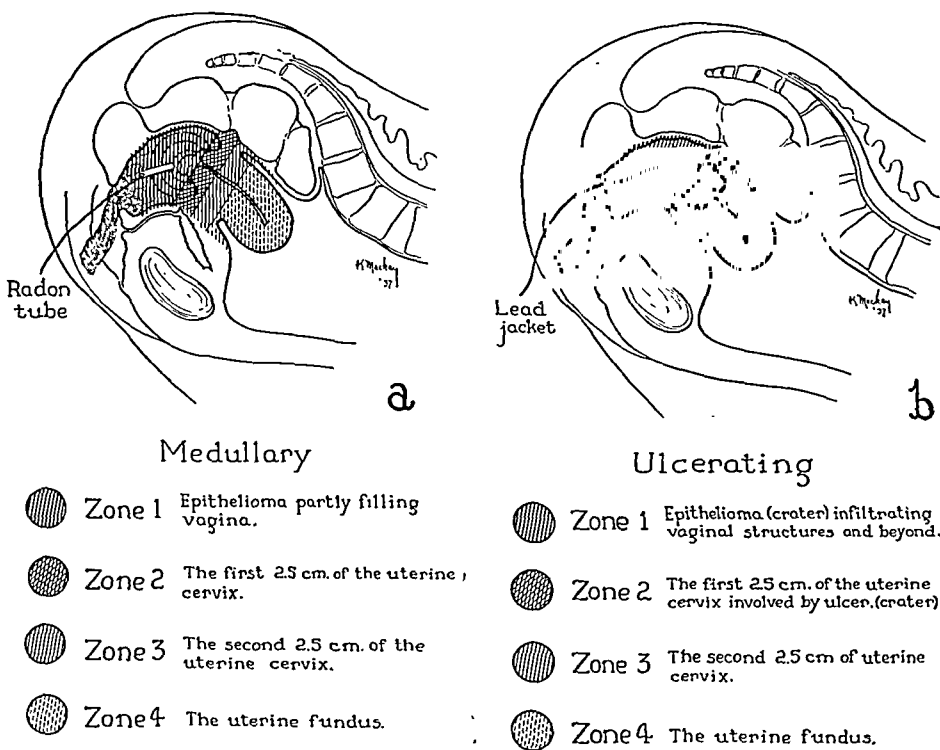

Fig. 1.—Treatment of (a) medullary type, and (b) infiltrating types of uterine carcinoma. Patient in knee-chest position and applicator in place.

(fig. 1). The intervals are necessary to determine the radiosensitivity of the treated lesion. In cases in which such complications as tumor necrosis, local cellulitis, ulceration of the vaginal walls that is indicative of potential fistulas, or pyometritis are present the intervals permit the proper institution of active measures to combat these serious, if not dangerous, conditions. In the final part of the course, the treatments are applied more rapidly. The other details are shown in figure 2, in which the probable treatment schedule for an average patient with a stage 3 involvement is outlined. The radium therapy is followed by a course of so-called high voltage roentgen therapy. The combined method of treatment was employed in 1,450 of the 1,491 cases in this series. In the remaining forty-one cases roentgen therapy was the only treatment used.

The classification of the courses of radium treatment is essential for their evaluation. In the event that the

1. Bowing, H. H., and Fricke, R. E.: Carcinoma of the Uterine Cervix: A Survey of Treatment and Results in 1,491 Cases, *Am. J. Roentgenol.* 40: 47-51 (July) 1938.

treatment is applied as outlined, together with any additional or probable reduction in the number of applicators, it is classed as complete. In some cases, owing to the character and extent of the local or pelvic involvement, only part of the outline can be carried out. In such cases the treatments are classed as limited. During the course of treatment it may become necessary to stop treatment and in this event the treatment is classed as abandoned. Table 1 shows the most significant factor in estimating the longevity of these patients; 52.9 per cent of the patients who received a complete treatment and 21.4 per cent of those who received only a limited treatment lived three or more years after treatment. This result is all the more significant because in more than 90 per cent of the 1,491 cases the involve-

the treatment may furnish an index. All treatable patients are benefited. The vaginal discharge stops, the tendency to bleed stops, and in many cases the relief of pain is prompt. The degree and the duration of this improvement depend on the extent of malignant involvement and the adequacy with which treatment can be applied.

The patient with stage 1 and modified stage 1 involvement has the best chance of living three or more years after treatment, while the patient who has stage 4 and modified stage 4 involvement has the least chance of living three or more years after treatment. In brief, all treatable patients have a chance of living three or more years after treatment (table 2). An evaluation of these results indicates that the extent of involvement

plays a major role in the determination of the longevity of the patient after treatment.

Grossly, there are two types of carcinoma of the uterine cervix; these usually are designated as (1) medullary carcinoma and (2) infiltrating or ulcerating carcinoma. The latter type predominates and is more radioresistant than is the former. The grade of malignancy cannot be determined from the gross characteristics of the lesion. However, the gross appearance of the lesion does determine the selection of the type of treatment to be employed in a given case. In other words, the estimation of the grade of malignancy is of but little if any assistance to the radium therapist in determining the treatment to be employed. This statement must be made with a certain amount of reservation because a low grade of malignancy seldom is encountered in cases of carcinoma of the uterine cervix and when it is en-

countered the neoplasm usually is an adenocarcinoma. It is doubtful whether a squamous cell epithelioma, grade 1, was ever encountered.<sup>2</sup> In other words, our experience centers around the predominating grade 3 and grade 4 lesions. It is evident that if a number of patients who have carcinoma of the cervix are treated individually, irrespective of the grade of malignancy, and if the patients later are grouped according to the grade of malignancy, there will be little difference in the number of three year cures obtained in the various groups. The data in table 3 are submitted to substantiate this statement. Forty per cent of the patients with lesions of grade 1 and 41.1 per cent with lesions of grade 4 lived three or more years after treatment.

Briefly, it seems possible to obtain the same radiotherapeutic result in the treatment of this disease regardless of the grade of malignancy, but one must

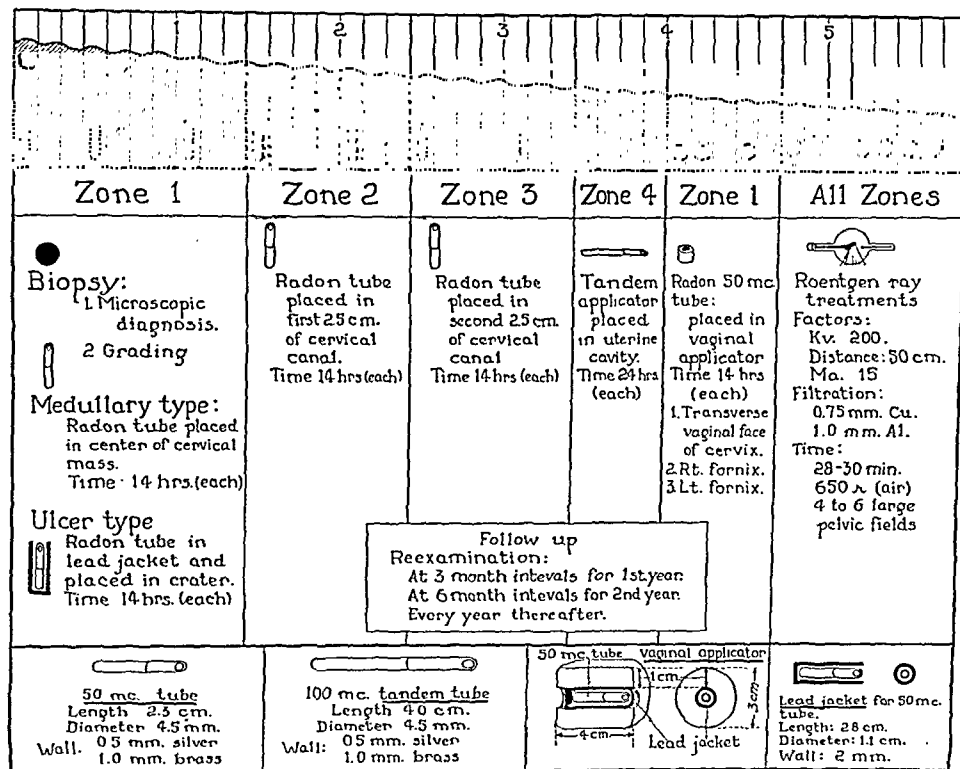

Fig. 2.—Schedule of radium treatment for the average stage 3 involvement in a case of carcinoma of the uterine cervix. Each of the Arabic numerals across the top of the drawing indicates the end of one week of treatment. The vertical line which is intercepted by each Arabic numeral, and every other similar vertical line, indicates the end of one day. The wavy line which descends from left to right indicates the decreasing infiltration and the general improvement of the patient's condition as treatment progresses. Directions for a complete treatment can be obtained by reading the chart from left to right.

ment was extensive (stages 3 and 4, table 2). The large number of patients who received limited treatments can be explained as follows. They were treated in the early years covered by this study and when compared with the patients treated in the later years of this study their therapeutic management was considered to be a limited treatment. Of the patients whose treatment was abandoned 30.3 per cent lived three years or more after the treatment (table 1). Much depends on the amount of treatment applied before it is necessary to stop the applications. The analysis of this group is fascinating; many of the patients who lived three or more years after the treatment received a very limited treatment. The associated complications may have been a deciding factor in the response to radium therapy.

We have no statistical data to confirm the statements made about the immediate or initial result. However, the patients who lived three or more years after

2. Broders, A. C.: Personal communication to the authors.

remember that the cases in which the grade of malignancy was low were very few in number and do not warrant a statistical review or opinion. These statistical data warrant further study. We are in accord with MacCarty's statement that one is prone to accept observations too quickly and is likely to draw premature conclusions; this especially is true of microscopic grading and sensitivity.<sup>3</sup>

In order to study the influence of age on the longevity of this group of patients they were grouped according

to their ages by decades (table 4). It is an accepted fact that young patients do not tolerate malignant disease as well as do older patients. In other words, the young patient with malignant disease has a poorer prognosis than does an older patient. The data in table 4 substantiate this statement. The number of three year cures of patients treated before the age of 49 years was less than it was of patients treated after the age of 49 years. Patients who were in the fourth and fifth decades of life when radiation therapy was started showed little difference in the percentage of three year cures; however, this statement does not hold true if the patients who were in the third decade of life are included. This may indicate that if it is possible to employ individual treatment for patients in the fourth and fifth decades of life the percentage of three year cures will be approximately the same in the two groups. The percentage of three year cures was increased for patients who were beyond the age of 49 years. It seems probable that age may influence the degree of radiosensitivity but it is possible that the primary lesion responds equally regardless of the age of the patient. However, if metastasis to distant organs occurs before the age of 49 years it may be the factor that reduces the number of three year cures. We do not have data that confirm or disprove this statement.

3. MacCarty, W. C.: Microscopic Grading of Tumors, Its Interpretation, Limitations and Relation to Radiosensitivity, *Am. J. Roentgenol.* 37: 365-367 (March) 1937.

A second significant factor occurs in the data contained in table 5. The patients treated early in our experience received a limited radium treatment, for example about 2,000 mg. hours, which may be considered a surface treatment. This was supplemented with the so-called low voltage roentgen therapy and the initial result was favorable; when the patients were seen after an interval of a few weeks, or months, however, activity was demonstrable. As a further palliative procedure the initial treatment was repeated. Many patients received several such treatments but, as a rule, malignant activity was demonstrated on subsequent visits. A careful review of these cases was encouraging but it was evident that the technic was deficient as it did not provide proper distribution of the therapeutic rays of radium, and the initial total dose was too small. For these reasons our present technic was evolved; this accounts in a great measure for the difference in results shown in table 5. Today an initial complete treatment is never repeated and the result is superior when compared with our early results. Of the patients treated between 1915 and 1919 inclusive 14.4 per cent and of the ones treated between 1925 and 1929 inclusive 42.7 per cent lived three or more years after treatment. The radium technic employed today began

to take form in or about the year 1920. We were favorably impressed with the early results, which encouraged us to persevere and perfect our present plan of treatment.

The hospital mortality was calculated on the basis of the type of treatment applied (table 6). There were 604 complete treatments with one death, a mortality of 0.2 per cent. There were 807 limited treat-

ments with five deaths, a mortality of 0.6 per cent. Every endeavor is made at the time the patient is first seen to select the best type of treatment to meet the therapeutic needs. In other words, every effort is made to avoid, if possible, abandoning treatments. When one considers the numerous applications made throughout the years, the risk attached to a single treatment must be very small; however, the cumulative effect cannot be ruled out. A limited treatment indicates an extensive pelvic involvement and poor general health; it naturally indicates that the risk of treatment would be increased. The hospital mortality in the cases in which the treatment was abandoned was 15.4 per cent. The hospital mortality in the entire series was 0.8 per cent.

## SUMMARY

The radiosensitivity of carcinoma of the uterine cervix is a relative feature and its significance must be fully appreciated in the therapeutic management of

this disease. If carcinoma of the uterine cervix and the associated inflammatory and degenerative process are effectively treated with radium and supportive measures, the result of treatment is prompt and its duration is evidenced by the percentage of three year cures. An attempt has been made to use the late results as an index of the radiosensitivity of the lesion. Patients possess many potentialities which affect the results of irradiation. The immediate result is influenced definitely by the extent of the malignant process. It is evident that the age and general health of the patient, the equipment and the skill and experience of the therapeutic radiologist have a definite influence on the late result. The best results are obtained in cases in which the treatment is classed as complete at the first session. However, subsequent treatment may produce relief that will last for years. The initial course of radium treatment requiring two, three or more weeks is necessary before one can evaluate the immediate results and determine the radiosensitivity of the lesion. An interval

of three months should elapse before one attempts to evaluate the late results. We fully appreciate the limitations of statistical data; however, the data in this paper are supported by our clinical experience.

## ABSTRACT OF DISCUSSION

DR. WILLIAM P. HEALY, New York: About 80 per cent of cancers of the cervix histologically are radiosensitive. Twenty per cent are in the adult group of cancer cells which are relatively radioresistant, but even those cases respond to irradiation because it is only a relative degree of resistance. It is for this reason that cancer of the cervix has gone out of the surgical group into the radiation field of therapy. Rarely is a case of cancer of the cervix encountered in which there is a limited degree of response to irradiation, but occasionally one will meet a case in which improvement occurs for a period of several weeks and the disease is still limited to the cervix and must be grouped as a favorable case clinically, and yet one finds that the cancer does not disappear under irradiation. That patient is incurable under any form of treatment. In this rare instance one is justified in doing a simple, complete hysterectomy, and while the patient lives, which will probably be two or three years, she will remain free from local evidence of cancer. Since all these patients have come for radiation therapy, the degree of radiosensitivity in the individual case is purely of academic interest. One makes a biopsy because one must have a histologic diagnosis in the case, but one is going to treat her with radiation therapy regardless of whether the cancer is of grade 1 or grade 2 and regardless of whether it is a squamous carcinoma or an adenocarcinoma. All cancers do better with radiation therapy in average or expert hands than with surgery. The important item is early diagnosis. If one recognizes these cases early, one has an opportunity of curing 60 per cent of the early group. At the Memorial Hospital we have had 3,500 cases of cancer of the cervix uteri, and we have been impressed by the advantages of giving x-ray therapy with the high voltage x-ray apparatus, 200 kilovolts, before radium is used. It is unfortunate that the authors used only a three year survival classification. That is much too short and is of only academic value, because for cures one must have at least a five year limit. An untreated patient with cancer of the cervix may live two years.

DR. HENRY L. SCHMITZ, Chicago: The paper of Drs. Bowing and Fricke concerns the prognosis and course of the disease in relation to the extent of the growth and the general constitutional condition. The study of the clinical extent of the growth called by the writers stages 1, 2, 3 and 4, either modified or unmodified, would be facilitated if the clinics would agree on the same definitions for each stage. It would then be possible to evaluate the end results of the various forms of treatment of carcinoma of the cervix. The widest differences are found in the definitions of clinical groups 1, 2 and 3. The difference between clinical group 1 and clinical group 2 cases is mobility of the uterus. It is normal in the former if one attaches a forceps to the uterus and it can be displaced down to the entrance of the vagina without causing the patient any distress. In clinical group 2 the uterus is limited in mobility, though movable, and it cannot be displaced downward unless one uses an appreciable pull. Limited mobility may be due to either an extension of the carcinoma or an inflammatory reaction in the pericervical tissues. It is clear that a patient with an inflammatory loss of mobility of tissue will do better than one with a carcinomatous invasion of the paracervicum. The clinical group 3 case is characterized by an invasion of either one or both parametria yet mobility of the entire mass is still present. There should be made a distinction between fixation and limited mobility of the tumor. As soon as the carcinoma becomes fixed, a clinical group 4 carcinoma is present. Presence of local or distant metastases, or invasion of adjacent organs as bladder, vagina or rectum in the absence of fixation, also stamp such a cancer as belonging to clinical group 4. Such a clinical grouping of the extent

of the growth is very important for the selection of the indicated form of treatment and for the study of the good end results. I do not wish to add to these definitions, as the proper grouping alone will enable one to select the treatment and to prognosticate the results.

DR. HENRY ULLMANN, Santa Barbara, Calif.: In the question of clinical stages 1 and 2—and Dr. Schmitz brought up the question of inflammatory reaction—I again want to emphasize, and trust that it will be brought out in the closing discussion again, that quite a number of patients whom I have seen that I would class as a 2, perhaps an early 2 because of a limited mobility, within a few days after a light course of roentgen treatment has been begun, had complete mobility and palpable induration of the immediate part of the broad ligaments. So that a clinical type 2, at first examination, becomes a clinical type 1 after some irradiation. I feel that perhaps we should add to this that a true class 2, type 2, in order to keep our statistics clear, must remain somewhat limited in mobility after a moderate dose of roentgen rays, because I do not believe that this dose will bring back the mobility so promptly unless it is due to inflammation and not to cancer.

DR. HARRY H. BOWING, Rochester, Minn.: Concerning Dr. Healy's discussion a misunderstanding has occurred, as no attempt was made to report the five year results. I did select the three year results obtained in the group of 1,491 cases for comparison to illustrate a few of the many factors that influence radiosensitivity. Briefly, the data on the 1,491 cases were arranged in tables to show the results according to the age of the patient, grade of malignancy (Broders), stage of involvement, the year of the treatment and the type of radium treatment. It is logical to assume that initial or early response to treatment of the primary lesion or, in other words, the radiosensitivity of the lesion, should also be reflected in the three year cures and that it should be possible to measure the duration of this response by an analysis of the three year cures. Naturally, the outstanding single factor governing the early and late results is the stage of the lesion at the time of treatment. In the cases in which the lesion was grade 1, 92.3 per cent of the patients lived three years, but in the cases in which the lesion was grade 4, only 12.7 per cent of the patients lived three years. There was a marked difference in the late result when the calendar year of treatment was tabulated. The technic of radium therapy has improved with the passing of the years. Of the patients treated in the early years of our experience 14.4 per cent lived three years, but of the patients treated in the last five years of this study 42.7 per cent lived three years. Evidently the improvement in technic favored or enhanced radiosensitivity. Adequate radium therapy is not possible in all cases, and as a result patients do not all obtain the same response. In this study 565 traced patients received a complete radium treatment and 52.9 per cent of these patients lived three years. Only a limited radium treatment was possible in 739 of the cases in which the patients could be traced; 21.4 per cent of the patients lived three years. Evidently the adequacy of treatment influences the radiosensitivity. The results according to age groupings are of great interest. The young and old patients are too few for analysis. Of the 458 traced patients who were between the ages of 40 and 49 years, 31.6 per cent lived three years; and of the 416 traced patients between 50 and 59 years of age 38.5 per cent lived three years. Evidently the older patients survive longer than do younger patients or radiosensitivity is influenced by the age of the patient.

**Special Institutions for the Insane.**—In summing up the movement for special institutions for the insane during the first quarter of the nineteenth century, we find such institutions being established in eight different states for the first time. Of these, six were founded as semipublic institutions by incorporated groups, and two were completely under state auspices. A ninth state, Virginia, established its second state hospital during this period.—Deutsch, Albert: *The Mentally Ill in America*, New York, Doubleday, Doran & Co., Inc., 1937.

## SODIUM CHLORIDE TOLERANCE IN CHRONIC NEPHRITIS

WITH SOME OBSERVATIONS ON THE  
POTASSIUM AND SULFATE IONS

M. HERBERT BARKER, M.D.

CHICAGO

AND

ROGER ROBINSON, M.D.

BOSTON

Work published a few years ago<sup>1</sup> on the effect of minerals on fluid balance in experimental nephrotic edema of dogs indicated that sodium entered into the formation of edema, whereas potassium acted to displace it. Further, that the chloride ion was not the active element in the storage of fluid but that it was able to facilitate the formation of edema by uniting with sodium. However, the chloride ion acted as a diuretic by drawing on stored base when administered in excess, such as ammonium chloride, and it was especially effective as a diuretic when given as potassium chloride. This led to a clinical trial of these observations which was found to be effective in many patients suffering with resistant cardiac and nephrotic edemas.<sup>2</sup> The low sodium, high potassium acid ash diet was developed, and 5 Gm. of potassium chloride was added daily for its diuretic effect and for its important assistance as a salt substitute. The past five years have further established the clinical value of this regimen in the control of such problems of edema.

Since in many cases of chronic glomerular nephritis hypertension, cardiac enlargement, gallop rhythm and edema develop late in the disease, a low sodium, high potassium neutral ash diet with potassium chloride was tried. In many instances the regimen was effective in relieving the edema, but too frequently there was a sharp aggravation of the uremic manifestations as an acidosis developed.<sup>3</sup> This led to further specific ion studies on such patients with the hope that additional information of late chronic renal disease might be obtained. Only a few of the observations made on these cases will be presented.

### METHOD

Fifteen patients who were faithful to the clinic with long-standing renal disease were sent into the research ward for a period of observation. They were placed on a diet which was found suitable to their taste and to their renal status, so that it could be completely tolerated for many weeks. The diet was then kept constant in nitrogen, phosphorus, sulfur, chloride, sodium and potassium so far as variable sources of individual foods permitted. The problem was carefully explained to the patients so that their complete cooperation was obtained except in one instance. They were kept ambulatory in the ward, sun porches and gardens, which kept them happy.

To this basic program, after a period of observation of from two to four weeks, additions of sodium

chloride, potassium chloride, sodium citrate, bicarbonate, potassium citrate, calcium gluconate or chloride, phosphoric acid or ammonium sulfate or combinations of these substances were given in amounts calculated for the individual patient. Changes in symptoms, blood pressure, edema, renal function and body chemistries were observed.

Daily weight, fluid intake and output, alternate day or biweekly blood chemical determinations were made

Chart 1.—The systolic and diastolic blood pressures increased sharply when sodium chloride. (the equivalent of 2 liters of physiologic solution of sodium chloride) was added to this diet otherwise constant in mineral content.

depending on the acuteness of the case. These observations consisted of the determination of sodium, potassium, calcium, chlorides, phosphates, sulfates, carbon dioxide combining power, urea, urea clearance, creatinine, serum proteins, hematocrit and fluid and blood volumes. Blood counts, phenolsulfonphthalein excretion tests, routine renal function tests, examination of the eyegrounds and chemical studies of edema fluid when present were made weekly as indicated. Blood pressures were taken twice a day.

#### RESULTS

The chief observations were those of the storage of fluid, aggravation of symptoms, elevation of blood pressure and decreased urea clearance when sodium was added to the basic diet. This was especially true of sodium chloride (chart 1). Chlorides administered as ammonium or calcium chloride or diluted hydrochloric acid frequently decreased the edema, but the associated acidosis aggravated the symptoms and depressed renal function. In certain cases presenting low blood chlorides following the forcing of fluids without a normal intake of chloride or following vomiting the chloride deficit had to be replaced, as Peters and his associates<sup>4</sup> have demonstrated. However, chlorides administered as potassium chloride usually effected a moderate or complete loss of edema and an occasional improvement of urea clearance. There was never a retention of potassium in the cases studied nor was there any evidence of potassium intoxication (chart 2). The administration of calcium orally or

intravenously did not produce sufficient changes for comment at this time. However, the addition of the acid ions of phosphate and sulfate were of special note. Both ions seemed to be effective occasionally in clearing edema and reducing blood pressure. The former, administered in its most palatable form—phosphoric acid—usually produced a hyperphosphotemia like that seen in acute nephritis or the end stage of chronic nephritis, with a resultant acidosis and aggravation of the renal state. The known seriousness of the storage of phosphorus in renal insufficiency was again clearly shown and the experiment with phosphate was soon discontinued. The sulfate, given as ammonium sulfate, had a much more satisfactory effect. Not only did the blood pressure fall and edema disappear in nine cases but urea clearance improved together with improvement of other subjective symptoms, such as loss of headache, nausea, vomiting and anorexia. Retinal edema and exudate, when present, was relieved. The latter point may be emphasized. Some observations may be more clearly indicated by reference to one of the records of a representative case.

#### REPORT OF CASE

A. B., a man aged 40, a carpenter, who had acute nephritis in 1931, continued to show urinary changes and a progressive diminution of renal function. Whenever he took salt or salt-containing foods the blood pressure would rise, the urea clearance would fall and edema would form. This state was attended by symptoms of severe headache, pounding of the heart and dyspnea; especially attacks of nocturnal dyspnea were noted whenever the blood pressure would rise over 200 mm. At the time of this study, the urine was acid, the specific gravity was from 1.010 to 1.008 and contained 2 plus albumin, from 4 to 20 red blood cells per high power field and a moderate number of hyaline and granular casts. The phenolsulfonphthalein excretion was 10 per cent and the urea clearance was 30 per cent of normal. There were moderate edema of the

Chart 2.—The administration of the potassium ion as potassium chloride and potassium citrate was associated with a diuresis and an improvement of urea clearance while a sharp depression of the urea clearance and a rapid collection of edema followed an equal amount of sodium chloride and sodium citrate. A return to the potassium salts resulted in diuresis and an improvement of urea clearance.

face and legs, slight arteriosclerosis and cardiac enlargement. The blood pressure was 160 systolic, 120 diastolic.

The diet was kept constant, as already described. Fifteen Gm. of sodium bicarbonate was given daily for two weeks at the beginning of the study as a further check on the sodium ion (chart 3). The chief finding aside from a rapid increase in the carbon dioxide combining power was a depression of the urea clearance until buffering doses of ammonium sulfate

4. Peters, J. P.; Wakeman, A. M., and Lee, Carter: Total Acid-Base Equilibrium of Plasma in Health and Disease, *J. Clin. Investigation* 6: 517 (Feb.) 1929.

were added. A period of two weeks was allowed for a return to whatever mineral balance this patient was able to regain. At that time 15 Gm. of sodium chloride was taken orally. Very soon there was a sharp decrease in urea clearance and there was a gradual increase both of systolic and of diastolic blood pressure. Symptoms of severe headache, depression, anorexia, heart consciousness, nocturnal dyspnea and stupor gradually developed. By this time the urea clearance had fallen to 10 per cent of normal and the blood pressure had reached 220 systolic, 165 diastolic. A rather dramatic arrest of this trend, followed by an improvement of the urea clearance and a drop

Chart 3.—Sodium bicarbonate administered to a patient with severe glomerular nephritis depressed the urea clearance slightly. When ammonium sulfate was added, the blood pressure decreased, and an arrest of the falling urea clearance was noted. An equal number of grams of sodium chloride substituted for the sodium bicarbonate caused a marked depression of the urea clearance and a sharp elevation of the blood pressure. The addition of a buffering dose of ammonium sulfate seemed to arrest the effect of the sodium chloride.

of the systolic and diastolic blood pressure, was attended by the daily addition of 5 Gm. of ammonium sulfate orally. There was a rapid improvement of all symptoms as soon as the sodium chloride was discontinued. An important sequel to this experiment was the continued symptomatic and clinical improvement attended by the continued administration of the ammonium sulfate. The patient complained of headache and a general feeling of ill-being, and there was storage of fluid and an increase of the blood pressure when the sulfate ion was discontinued. When the ammonium sulfate was resumed, not only was the patient generally improved but small amounts of salt could be taken on the food without precipitating a renal crisis as that described.

#### COMMENT

Careful clinical and metabolic studies of fifteen selected cases of advanced renal disease have shown marked elevations of blood pressure, decreases of renal function and associated symptoms in nine cases whenever sodium chloride was ingested. The many sources of sodium chloride in common foods that the salt-hungry patient will naturally select when he is on a salt-free diet renders true restriction of sodium chloride very difficult. Considerable comfort and security may be gained for the occasional patient by giving potassium chloride as a salt substitute, as previously reported. These studies suggest that when one is forced to go on a low protein diet one gives up not only protein but the phosphate and sulfate ions of the meat that play an important role in fluid balance. This factor is no doubt important in the diuretic effect of the high-protein diet frequently given the nephrotic patient. It is further shown that the chronic nephritic patient is readily upset by changes in his mineral intake, apparently because of poor mineral metabolism or clearance.

Certainly he is thrown into an acidosis or an alkalosis very easily, either extreme being dangerous. The retention of phosphorus and its effect on acid-base equilibrium with aggravation of the uremic state is emphasized. Further, the possible beneficial effects of the sulfate ion as ammonium sulfate administered in doses of from 2 to 6 Gm. daily was noteworthy in these cases. Although the buffering or neutralizing effect of sodium or some other specific function was not demonstrated in this study, its possible therapeutic value suggests further critical observation. Two patients were unable to clear sulfate readily, and an intoxication and acidosis was noted. The blood sulfates rarely increased over 3 mg., the highest being 7.8 mg. per hundred cubic centimeters. It is obvious, therefore, that although the beneficial effect of ammonium sulfate may be great, its retention must be considered. Since the low protein diet leaves the patient chiefly fruits and vegetables, which supply base in great excess, the need for nontoxic, nonthreshold neutralizing acid elements may be desirable. Ammonium sulfate has been the most helpful of the substances used. Not only is the patient who is required to take a low protein, salt-free diet kept in a better state of urea clearance, circulation and fluid balance, but the addition of ammonium sulfate may permit the taking of small amounts of salt, which renders the diet more palatable. Further, it may cover the sodium chloride, which most certainly will creep into one's food with the disastrous effects demonstrated.

700 North Michigan Avenue.

#### ABSTRACT OF DISCUSSION

DR. THOMAS ADDIS, San Francisco: This paper is definitely of an experimental nature and so I hope that when the paper is published the authors will make it clear that they are not recommending a low sodium, high potassium diet for all patients with chronic nephritis. It is safe enough for the authors to do it in certain special situations but it wouldn't be safe for the rest of us to use it in all cases. In fact, nothing could be more dangerous than such a diet for patients who are approaching the uremic level, because there one is dealing with a situation in which there is already a strong tendency to lose sodium on account of decrease in renal reabsorption of sodium; and when that is accentuated by any exceptional loss of sodium such as may be produced by vomiting, and it occurs in a patient who is already on a low sodium diet, then unquestionably conditions exist that favor acute renal failure, from which one may save the patient by actually giving him sodium. With respect to a high potassium diet I have a suspicion that in patients who are approaching the uremic level that also may be dangerous. The reason is that I have been making some observations on rats in which an experimental form of uremia had been produced by tying the vena cava. It was found that meat was very toxic to these animals; it increased the mortality. It was natural at first to suppose that this was due to some organic substance associated with the protein in the meat, but further analysis of the situation forced the conclusion that it was really the high potassium content of the meat, not any organic constituent, which was mainly responsible for the increased mortality. And that observation has been verified under altogether different conditions by Dr. Drury at the University of Southern California. Quite independently he came to exactly the same conclusion. I am therefore asking the authors to make it very clear to those who are treating the glomerular nephritis that a low sodium, high potassium diet is no general prescription and that it can be used only under known and highly specific conditions.

DR. WILLIAM DOCK, San Francisco: Dr. Addis has emphasized that when glomerular nephritis begins it does so in an acute form which later ends in uremia and in a few cases in

heart failure. It is in the group having hypertensive heart failure and edema that this diet has been found useful and sodium harmful. When there is vomiting, nausea and finally uremic coma this diet may not be valuable, and in some cases sodium chloride actually seems to be of some use. The point that interested me particularly about this work is that it precedes, or perhaps one might say parallels, some other work that I have been interested in, namely the treatment of hypertension, benign hypertension preferably, by giving the patient an equivalent of Addison's disease. If one can combine a low sodium intake and a high potassium intake, perhaps with salt deprivation, one can produce by giving fairly frequent doses of a mercuric diuretic something equivalent to the Goldblatt hypertensive dog with its adrenals removed. In that state the dog is no longer hypertensive. I hope that the authors will extend their observations to benign hypertension and see to what extent a high potassium, low sodium intake, combined perhaps with further loss of sodium produced by mercuric diuretics, would aid in the control of that particular disorder. Of course, one reason they haven't done this is that his method of treating hypertension with thiocyanate is more effective than most methods that the rest of us have. It is natural therefore that Dr. Barker should be the last to be interested in another way of treating hypertension. In our laboratory we have seen the effect of Dr. Addis's treatment with a low salt diet, a modification of the old French or Allen methods of treating hypertension, which certainly is the most effective form of therapy. As the authors have shown, one must control the diet very rigidly. It isn't enough to tell the patient to stop taking salt. The effect of pushing that therapy to its logical conclusion, in the light of the effect of adrenalectomy on Goldblatt hypertension, should be settled within the near future. A few years ago we might have said "it isn't the hypertension that does the harm, it is the fact this patient has some toxin circulating which gives the hypertension and does the real damage." But the work with the Goldblatt dog shows conclusively that, if the hypertension can be controlled, the whole process will be greatly modified. Since the attack by surgery from the neurologic angle has not been brilliantly successful, other metabolic approaches certainly now seem very inviting.

DR. A. A. HEROLD, Shreveport, La.: The previous speaker talked of the old days of handling nephritis. Twenty years ago I was associated with a man of large experience and good ideas, and in those days the literature was full of the harmful effects of the chlorides in nephritis, and especially with edema. He said to me "It is not the chloride but the sodium radical which is doing the harm" and he suggested to me to use calcium chloride as a substitute for sodium chloride. We found a marked amelioration in the symptoms: toxicity was lower, and the edema almost invariably disappeared by substituting calcium chloride for sodium chloride in the food. That was before the days of the modern substitutes for sodium chloride which now are on the market. But by using small quantities the food was kept from being insipid. The patients got the necessary amount of chloride this way but were deprived of the sodium salt to that extent. While large quantities of the calcium chloride have a bitter taste, a smaller amount cannot be told from sodium chloride. I should like to ask the authors to state whether they have had any experience with the calcium salt and also to tell about their investigation with potassium salts.

DR. M. HERBERT BARKER, Chicago: As Dr. Addis has brought out, it is to be emphasized that this is an experimental observation, but it has definite therapeutic value in the selected case. We selected fifteen cases from a group that had been shown to be particularly sensitive to sodium chloride. No definite reason has been demonstrated for this marked sensitivity. Some individuals with a late chronic glomerular nephritis will show dramatic changes in blood pressure and urea clearance when they get salt, whether by eating anchovies, olives or Hungarian goulash; it doesn't matter where they get it. The chronic nephritic patient does not stand the resulting high blood pressure for any great period of time. We have used potassium chloride considerably, and I know

it is dangerous if given fast intravenously or if it is retained in the body. I do not have the fear of potassium that is expressed by some workers. That is probably due to the fact that we have been fortunate in not having potassium intoxication. Clinically potassium chloride has been very well tolerated in the majority of our patients during the last period of ten years during which we have been studying it. Now about the diet in Dr. Addis's rats. I should like to know what the phosphorus level was in the rats that were given meat, because in our work phosphorus was the death-dealing element when protein was administered and not the potassium. As for Dr. Dock's point about low sodium, high potassium in the hypertensive patient, it was immediately suggested when the low potassium, high sodium work came out a few years ago in the treatment of Addison's disease. We have done nothing with this phase of the minerals but it ought to be settled. As to the relation of calcium chloride, we have used it and have not found it notably helpful. We have felt that potassium chloride really entered into the system when chloride was needed and was much more satisfactory than giving the calcium salt, which is broken down in the intestine and the calcium goes out, leaving a free chloride ion which may throw some patients into an acidosis.

## TORSION OF THE TESTICLE

JOHN K. ORMOND, M.D.

DETROIT

Torsion of the spermatic cord is now a well established clinical entity, but the individual practitioner meets it so infrequently that in a large proportion of cases it goes unrecognized.

The first authentic report was by Delarsivue in 1840. In 1936 Abeshouse<sup>1</sup> was able to find 350 instances reported in the literature, which he summarized in a splendid and exhaustive article. The largest individual series were eighteen cases reported by Terazzi and nine cases by O'Connor.<sup>2</sup> To date twelve instances of this condition have come under my observation, two of which have previously been reported.

Although the condition is uncommon, its recognition is of considerable importance, for failure of recognition may result in a testicular atrophy which might have been prevented, and this assumes greater importance in view of the fact that in twenty-four of Abeshouse's 350 cases the condition was bilateral. It is undoubtedly true that in some of the instances of testicular atrophy encountered in the course of routine physical examination the disease is due to previous and usually unrecognized torsion. Atrophy of the testicle is usually due to mumps, trauma (including operation for hydrocele, hernia or varicocele) or torsion. The atrophic testicle of mumps is usually soft and extremely sensitive, while that due to trauma or torsion is firm and insensitive. The undeveloped testis is small and soft but not unduly sensitive.

Torsion has been observed in every decade of life from infancy to old age, though most commonly in adolescence or early adult life. It apparently occurs about as often on one side as on the other, but definitely oftener with maldescent of the testicle than with

From the Henry Ford Hospital.  
Read before the Section on Urology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

1. Abeshouse, B. S.: *Torsion of the Spermatic Cord: Report of Three Cases and Review of the Literature*, Urol. & Cutan. Rev. **40**: 699 (Oct.) 1936.

2. O'Connor, V. J.: *Torsion of the Spermatic Cord: Report of Two Cases and Review of the Literature*, Surg., Gynec. & Obst. **29**: 580 (Dec.) 1919; *Torsion of the Spermatic Cord*, *ibid.* **57**: 242 (Aug.) 1933.

complete descent. In this connection it is interesting to note that eleven cases of torsion of an intra-abdominal testis are on record.

Two types of torsion are described, intravaginal and extravaginal. Of these the intravaginal type has been observed much oftener than the extravaginal.

In intravaginal torsion the twist in the cord is within the tunica vaginalis and involves the testis and epididymis but not the tunica. Ordinarily the reflection of the parietal layer of the tunica over the epididymis forms a "mesentery" (mesorchium) running from the globus minor to about the middle of the globus major. In many recorded cases this has been much shortened, including only the globus major and hence predisposing to torsion, which may follow slight muscular strain or effort and not necessarily require unusual force.

In extravaginal torsion the twist occurs in the cord outside the tunica and the whole testicular mass is involved. This is often caused by gross violence, though a strong contraction of the cremasteric muscle is said sometimes to cause it.

The first effect of rotation is flattening of the veins and partial obstruction of the venous return; then, as the rotation continues, there occurs obliteration of the veins and finally obliteration of the artery. The effect on the testicle depends on the degree of torsion. If the venous return is not completely obstructed there will be congestion and edema, especially of the epididymis, which is more distensible than the testis. If the venous return is entirely obstructed, congestion is greater and necrosis occurs in a short time. Of course if the twist is sufficient to obliterate the artery prompt infarction occurs.

In some instances, at operation the testicle has been found to be necrotic but no torsion has been demonstrable. In view of the typical character of the attack, it is probable that in these cases torsion had occurred and detorsion had taken place after necrosis had resulted. If detorsion is brought about soon enough necrosis or atrophy may be prevented, though repeated incomplete torsion by causing repeated congestion may eventuate in atrophy.

The majority of cases reported in the literature are of complete strangulation with resultant gangrene. Since the symptoms are severe, operation has often been performed, usually orchidectomy. In some instances, however, detorsion has been possible when the condition was seen early, and there are a few instances of repeated attacks of incomplete torsion with spontaneous detorsion and a smaller number in which attacks of incomplete torsion recurred over a fairly long period and were repeatedly treated by manual detorsion. We have seen these types.

The direction of the twist is not always the same, but O'Connor stated that in the majority of acute attacks the twist has occurred from within outward.

Diagnosis presents some difficulties, especially in the first attack and when, as usually occurs, the patient is seen in one attack only.

The onset is usually sudden and has occurred during sleep, awakening the patient. More often it follows effort or slight and seemingly inadequate trauma, such as that due to diving or bicycle riding. The pain is sharp, its intensity varying with the completeness of the twist. A history of previous similar attacks, clearing up spontaneously, is of extreme importance and almost diagnostic when obtained, and the absence of any history or symptoms of gonorrhea is important.

General symptoms may include nausea, vomiting and occasionally shock. Usually there is no fever, though there may be a slight elevation of temperature. There is usually no leukocytosis.

The urine is generally clear, and urinary symptoms are usually absent. The prostate and seminal vesicles usually present no abnormalities, though there is nothing to prevent torsion from occurring in a man whose prostate is infected.

The affected testicular mass will be found drawn up toward the inguinal region and is usually exquisitely tender, often so tender, in fact, as to prevent satisfactory palpation. Determination of the position of the epididymis is of importance. Normally the epididymis lies posterior and medial to the testis, but in the case of torsion, unless the twist is through 360 degrees or any multiple of 360 degrees the epididymis will be in an abnormal position. The degree of swelling varies and may be great enough to prevent differentiation of the parts of the mass. Therefore the position of the epididymis sometimes cannot be ascertained either because of the swelling or because of the extreme tenderness of the testicular mass. On the other hand, in attacks of recurrent torsion the obstruction to circulation is not complete and the swelling may be confined to the epididymis, making recognition of its position fairly easy.

Elevation of the scrotum is said to accentuate rather than to relieve the pain, as it does in cases of epididymitis, and Prehn called this a characteristic and almost diagnostic sign.

Torsion has been mistaken for acute epididymitis, acute orchitis, strangulated hernia, suppurative inguinal adenitis, acute hematocele and ureteral calculus.

Of these conditions the most important is epididymitis, and the differential diagnosis occasionally presents some difficulty, especially in cases of epididymitis following trauma. In this connection I have reviewed the cases of so-called traumatic epididymitis which I have observed, to learn whether any of them might have been instances of torsion. In some cases the observer's notes were inadequate for a certain diagnosis at this late date, but it seems to me significant that in only one instance labeled traumatic epididymitis did atrophy of the testicle result, and that was a case of rather extensive trauma to the suprapubic region, scrotum and thigh, accompanied by marked swelling and the formation of hematoma.

In epididymitis the pain is not so sudden or so severe as in torsion; there is usually evidence of infection in the urine, prostate or seminal vesicles or a history of recent urethritis; the temperature is more apt to be elevated, and the epididymis is apt to lie in its normal relationship to the testicle and is likely to be firmer and larger than in torsion. Also in epididymitis the tenderness tends to be localized to the region of the epididymis, while in torsion the whole mass is equally tender. Again, in epididymitis there is likely to be tenderness and swelling of the vas, and elevation of the scrotum relieves rather than accentuates the discomfort. Moreover, at the age at which torsion is most common, epididymitis is uncommon.

Orchitis except as a complication of mumps and occasionally of influenza is rare; the pain is not usually severe, and the swelling, though extensive, does not involve the cord.

Torsion has occasionally been mistaken for strangulated hernia, and the differential diagnosis may be dif-

ficult, for an undescended testicle is more apt to be affected by torsion than a fully descended one and is commonly accompanied by a hernia. Of course the general symptoms of strangulated hernia are more severe than those of torsion, and they grow progressively more severe while those of torsion progressively ameliorate. Both conditions require prompt treatment, and at operation all doubt will be resolved.

Confusion with suppurative inguinal adenitis has been reported a few times. The absence of the testicle from the scrotum and the absence of any infection draining to the inguinal glands (chancroid, for example) should put one on the right track.

In one of our cases the diagnosis of acute hematocele was made first. The patient was seen late, three days after onset, at which time there were marked swelling and discoloration. A few similar instances are on record. With hematocele the pain is never so severe and there is not the retraction of the testicular mass seen with torsion.

Prompt diagnosis is important, for on it may depend the health of the affected testis. Of course if the twist has been sufficient to cause infarction, delay makes no difference; but if the patient is seen before necrosis has occurred, prompt diagnosis and prompt treatment may preserve the life of the affected testis.

The best treatment is immediate operation. The scrotum should be incised and the testicle delivered. If it is necrotic, it can then be removed; if it is not necrotic and if the twist is in the cord, the torsion can be relieved, and if it is intravaginal, the tunica can be slit and the twist reversed. In any event it is best to incise and invert the tunica and then suture the cord and testicle to the scrotal septum in such a way that torsion becomes impossible.

Sometimes spontaneous detorsion occurs, and sometimes manual detorsion is possible without incision; but in either event operation shortly thereafter is desirable to eliminate any possibility of recurrence.

In the majority of recorded cases, necrosis had occurred and either orchidectomy was done or atrophy followed.

In view of the fact that in twenty-four of 350 cases on record the condition was bilateral, and in view of the fact that congenital abnormalities such as might predispose to torsion tend to be bilateral, I advocate operation on the remaining testicle to prevent a like misfortune involving it.

#### REPORT OF CASES

CASE 1.—A youth aged 19, half an hour after doing some high diving, noticed an aching sensation in the scrotum. This was followed by marked swelling but not by discoloration. Examination three days later showed marked enlargement of the scrotal contents on the left side with extreme tenderness which made accurate examination impossible. The temperature was 99 F., and there were no general symptoms. The swelling gradually receded, and the patient returned to school. Two years later physical examination showed the left testis atrophic, firm and insensitive.

It is possible that, had this condition been recognized immediately, prompt operation would have saved the testis.

CASE 2.—A youth aged 17 for six years had recurrent attacks of pain and swelling of the left testicle. The symptoms came on suddenly, disappeared rather quickly and were not associated with fever. At the end of the last attack, as it was subsiding, the testicle swelled again and there was a temperature of 101 F. When I saw the testicle three months

later it was still larger than the right and was firm, somewhat irregular in shape and insensitive. The Wassermann test and the Aschheim-Zondek test were negative. It is my impression that the patient had recurrent attacks of incomplete torsion, eventuating in an attack of complete torsion with gangrene and probably infection.

There was every opportunity of saving this testicle by operation, either during an attack or between attacks. I have advised a prophylactic operation on the other testicle.

CASE 3.—A boy aged 13 awoke one morning with pain in the left testis without any apparent cause. A few hours later, when he was examined, there were moderate swelling and exquisite tenderness of the left testis. The seminal vesicles were not palpable, and there were no urinary symptoms. A diagnosis of torsion was made and an attempt made to untwist the testis. This was unsuccessful and apparently increased the pain. Operation was therefore performed, about twelve hours after the onset of symptoms. At operation the testis was found to be mottled but not black. There were two twists of the testis on the cord, and these were released; the testis was replaced and sutured in such a way that torsion would be impossible in the future. This testis is now shrunken to half the size of the other and is firm and insensitive. Since then I have operated on the other testis and have sutured it in such a manner that a twist would be impossible.

It might have been wiser in this case not to have attempted manipulative detorsion and to have operated immediately, though the probabilities are that the torsion was complete from the first.

CASE 4.—A man aged 22 while doing some heavy work noticed pain in the right inguinal region, and later swelling appeared. There were no fever, no history of venereal disease, no abnormality of the prostate or seminal vesicles and no urinary symptoms. The right testicle was markedly swollen and tender. At operation the epididymis was found to be anterior to the testicle; both testis and epididymis were dusky, especially the epididymis, and neither bled when punctured. The testis was removed and found to be completely infarcted.

I would now advise operation on the other testicle.

CASE 5.—A boy aged 7 years for several weeks complained repeatedly of discomfort in the right side of the scrotum, which was relieved on some occasions by lifting and rotating the testicle. In one attack the testicle became somewhat swollen, and operation was decided on. At operation the right testicular mass was found to be twice normal size. The tunica was thick and edematous, and the testis lay within it, upside down. The tunica was inverted about the cord, and the cord and testis were sutured to the septum. The boy has been completely relieved of symptoms and the testis seems normal.

CASE 6.—A strong, well developed boy of 13 noticed an ache in his lower left quadrant after a boy scout hike, and his left testicle became swollen, tense and tender. His physician advised a suspensory. Two weeks later, when seen by me, the left testicular mass was three times normal size, tense, firm and not at all tender and did not transmit light. A month later it was about normal in size but was unduly firm. The patient has not been heard from for eight years, but the testis is probably atrophic.

I would now advise operation on the other testis.

CASE 7.—A man aged 38 without any apparent reason had pain in the right groin which later involved the right testis. When he was first seen, a week later, his temperature was normal, his urine was clear, there was no urethral discharge and the prostate gave no evidence of infection. The right testicle was held high in the scrotum, and the epididymis was somewhat swollen, firm and tender and lay somewhat lateral to the testis. Ten days later the epididymis was still enlarged and a little indurated.

In the absence of any evidence of infection, I considered this a case of incomplete torsion.

CASE 8.—A man aged 34 noticed one night that without cause his left testis had swelled and become tender. The next day the swelling became less and the tenderness largely disappeared. The epididymis was found to be somewhat swollen and lay lateral to the testis. Four days later there was no abnormality.

This was undoubtedly a case of partial torsion, with spontaneous detorsion. The patient has not been seen for six years. Under similar circumstances I would now advise operation to prevent recurrence.

CASE 9.—A young man aged 19 was seized with sudden terrific pain in the left lower quadrant of his abdomen, with no apparent cause, and became nauseated and vomited. There were no urinary symptoms. He was rushed to the hospital by his friends. Examination showed slight tenderness in the left lower quadrant. The left testis was drawn up high in the scrotum and was extremely tender. The cord and testis were manipulated, with spectacular and immediate relief of symptoms. He has not returned for observation but two years later is reported to be in good health and to have had no more attacks. I have advised him to have the testis operated on to prevent recurrence.

CASE 10.—A boy aged 4 years was brought in by another physician with a diagnosis of strangulated testicle. Operation showed torsion and infarction. The testicle was removed.

In such a case I would now advise operation on the other side.

CASE 11.—A physician aged 27 complained of a sudden attack of epididymitis and gave a history of repeated sudden attacks of pain and swelling of the left testis, with recovery in a day or two. The attacks usually followed slight trauma, though in a few instances there was no exertion or trauma to explain it. There had been at least twenty-five attacks during the past twelve years, and the patient had consulted many physicians, surgeons and urologists, who had all made a diagnosis of epididymitis. He was seen by us in three attacks and was taught to undo the twist immediately after it occurred. There was always one complete twist clockwise. He has been so successful in detorsion that, although there have been several attacks since, he has never come in for the operation which was recommended.

CASE 12.—A man aged 42 complained of pain in the right side of the abdomen, which had come on suddenly two days before, during coitus. The pain had been intermittent, had not radiated and had not been accompanied by urinary symptoms or by nausea or vomiting. There was no history of previous attacks. There was some tenderness and muscular resistance on the right side of the abdomen, with its maximum in the region of McBurney's point. The right testis was absent from the scrotum. A McBurney incision was made and a mass found consisting of a black and swollen testis, with one complete twist to the pedicle. It was removed with the appendix, which showed signs of mild chronic appendicitis.

#### SUMMARY AND CONCLUSIONS

I have reviewed briefly the symptoms and results in cases of torsion of the testicle and have reported twelve new cases. I wish to emphasize the importance of prompt recognition of this condition and would stress the following elements in the diagnosis: 1. The age of the patient. In this series eight patients were under 23, the youngest being 4 years old and five being adolescents. 2. The sudden onset. 3. The severity of the pain. 4. The absence of history or evidence of genito-urinary infection. 5. The position of the affected testicle in the scrotum. 6. The position of the epididymis with reference to the testicle. 7. The tenderness of the testicle. 8. Prehn's sign.

Finally, I would emphasize my conclusions regarding treatment. I believe that in an acute attack prompt

operation offers the best chance of a healthy testicle; that even though an attack is relieved by manual or spontaneous detorsion, operation should be done soon to prevent recurrence, and that if, because of torsion, a testis has become atrophic or has been removed, operation should be done on the remaining testis to prevent a like fate befalling it.

#### ABSTRACT OF DISCUSSION

DR. ROGER W. BARNES, Los Angeles: Torsion of the testicle is probably undiagnosed more often than it is recognized. Not long ago a patient was referred to me, and both the referring pediatrician and the hospital house officer stated that he had never before heard of the condition. Dr. Ormond's report of twelve cases shows that he has been on the alert to recognize the condition. I should like briefly to report a case in which there were unusual symptoms. A boy aged 14 was awakened by a sudden severe pain in the left testicle. A physician was called, who found the testicle extremely tender and slightly swollen and the cremasteric muscle contracting and relaxing so that the movement of the scrotum was very noticeable. The next morning the pain in the testicle was still present but not severe. The patient, however, complained of frequent urination and urgency and of having noticed some blood at the end of urination. The temperature was 103 F., and further examination showed the testicle to be very tender but no larger than it had been the night before. There was considerable tenderness in the lower left part of the abdomen just above the groin. When I saw the patient that afternoon the temperature was 101.2 F., and the other manifestations were approximately the same as those observed in the morning. The testicle was tipped somewhat upward, so that the isthmus of the epididymis was below instead of posterior to the testicle. Urinalysis showed many red blood cells, an occasional pus cell and a few gram-negative rods and gram-positive cocci. A roentgenogram showed no evidence of urinary calculi. The leukocyte count was 9,200. At operation some edema of the cord was found, but no torsion was present. The testicle was somewhat congested but otherwise normal. Fixation of both testicles, as Dr. Ormond has advised, was done, and the boy made an uneventful recovery. I am not certain whether some other pathologic process produced the fever, the tenderness in the lower left part of the abdomen and the blood in the urine, or whether these manifestations were all due to the torsion of the testicle. I should like to have Dr. Ormond's opinion regarding this.

DR. JAMES A. MAY, San Diego: Dr. Ormond has given a comprehensive discussion of torsion of the testicle. The twelve cases which he has reported constitute a rather large individual series and give his paper especial value and interest. There has been considerable speculation regarding the underlying etiologic factors in torsion. A thorough knowledge of the embryologic development of the testis and the mechanism of testicular descent is necessary for a complete understanding of the abnormal anatomic characteristics. The predisposing factors, according to Hinman, are (1) an anomaly of the tunica vaginalis which may be too large or have too high an insertion on the cord or an abnormal reflection from the epididymis; (2) absence or too great length of the gubernaculum; (3) an unusually low insertion of the cord; (4) an anomaly of the attachment of the epididymis to the testicle making the mesorchium loose or too short, and (5) an anomaly of the attachment of the testis and epididymis to the scrotum, so that this attachment is too loose. A voluminous tunica vaginalis per se would not seem to be a logical etiologic factor if one may judge from the frequency with which hydrocele occurs. I believe that the abnormal reflection from the epididymis is a much more important factor, in that it allows the testicle and the epididymis to hang in an intravaginal position which invites torsion. Absence or too great length of the gubernaculum does not seem to constitute a logical offender, since intermittent testicular retention is common in boys. The abnormal or loose attachment of the epididymis to the testicle, which causes the testicle to hang in an eccentric manner, is a much

more important factor. In addition, there are external factors which concern the force that precipitates the twist. Violent trauma, such as a direct blow, may tear the testicle loose from its scrotal attachments, thus permitting torsion to occur. Torsion has followed walking, heavy lifting, sneezing or straining at stool. It has also occurred during sleep. Many writers believe that a strong contraction of the cremasteric muscle initiates the twist, but this cannot be considered a factor in the causation of abnormally retained testes. The conclusion regarding the cause of torsion is that no one factor is responsible in all cases and that several factors may play a part in any one case.

DR. JOHN K. ORMOND, Detroit: I have never seen a case like the one described by Dr. Barnes. Hematuria has not occurred in any of the cases I have observed. Dr. Barnes's emphasis on teaching is apropos. I thank Dr. May for his discussion of the cause, which adequately complements my paper.

## EXCRETION OF SULFANILAMIDE AND ACETYSULFANILAMIDE IN HUMAN MILK

SHERMAN S. PINTO, M.D.

OMAHA

With the introduction and widespread use of sulfanilamide in the treatment of puerperal infections, much work has been done on the effect of the drug on the sick mother.<sup>1</sup> The excretion of the drug in men and in nonlactating women has also been studied extensively,<sup>2</sup> but I have been unable to find any work on the excretion of sulfanilamide in the lactating human mother. This work was undertaken to study the possibility of excretion of sulfanilamide in human milk and to determine, if possible, the amount of both sulfanilamide and the conjugated form of sulfanilamide which are known to be present in human blood<sup>3</sup> and, therefore, could possibly be present in human milk.

### PROCEDURE

The method described by Marshall<sup>2</sup> in which alcohol is used as a protein precipitant cannot be applied to milk because of the high fat content of milk. An appreciable amount of fat is dissolved by the concentrated alcohol and later is precipitated during the process of diazotization. In cow's milk, the method described by Fuller,<sup>4</sup> in which trichloroacetic acid is used as a protein precipitant, works satisfactorily. Apparently there is enough protein present so that the fat of the milk is enmeshed by the protein coagulum, and fat and protein are removed at the same time. In human milk the ratio of fat to protein is much higher, and the protein precipitants that I used failed to form a coagulum which would at the same time enmesh and remove all the colloidal fat. I have overcome this difficulty by making the analyses on "skimmed" human milk. The milk is centrifuged for ten minutes at 3,500 revolutions per minute. Sulfanilamide added to human milk has been recovered quantitatively from the skimmed portion

of the milk, and none was lost by dissolving in the fat which was removed by centrifugation. Since the fat content of the milk in the "cream" layer varied from 3 to 4.5 per cent, it was found more satisfactory to report all results in terms of "skimmed" milk. Diazotization of the sulfanilamide with dimethyl-alpha-naphthylamine was used because the color produced was extremely sensitive to small variations of the sulfanilamide content of the sample undergoing examination. Certain conditions were found to produce maximum color, deviations from this optimum resulting in lessened color production. The conditions for optimal results are that (1) the solution should contain 0.01 normal hydrochloric acid, (2) the solution should contain 47 per cent alcohol and (3) the trichloroacetic acid concentration should be kept as low as possible because it retards the diazotization process. To 1 cc. of skimmed milk are added 1 cc. of 20 per cent trichloroacetic acid and 2 cc. of water. The mixture is filtered, and 2 cc. of the clear filtrate is pipetted into a 15 cc. test tube. To this are added in succession 1 cc. of tenth normal hydrochloric acid, 5 cc. of 95 per cent alcohol, 1 cc. of 0.1 per cent sodium nitrite and, after waiting three minutes, 1 cc. of the dimethyl-alpha-naphthylamine reagent. (The dimethyl-alpha-naphthylamine reagent is made by dissolving 1 cc. of dimethyl-alpha-naphthylamine in 95 per cent ethyl alcohol and diluting to 100 cc.) A suitable standard should be prepared at the same time. It is important that the standard should also contain trichloroacetic acid, for this imparts an orange tinge to the final color, thus facilitating the color comparison. Maximum color development occurs in thirty minutes and remains constant for several hours.

It has been shown that, at least for dogs, acetylsulfanilamide is more toxic than free sulfanilamide. Therefore, I have extended my studies to include determination of this substance in human milk. When a protein-free filtrate of milk, prepared by using trichloroacetic acid, is heated with normal hydrochloric acid to hydrolyze the acetylsulfanilamide compound, the solution turns brown after about ten minutes heating at boiling temperature. I found that this charring is due to some substance or substances which are removable by treatment of the filtrate with copper sulfate-calcium hydroxide, as is done for the removal of carbohydrates. To use copper sulfate-calcium hydroxide for the removal of protein and carbohydrate, as is done for the determination of lactic acid in milk, is not suitable, since some substance is left in solution which is precipitated by the alcohol at the time of diazotization of the sulfanilamide. I found that the copper sulfate-calcium hydroxide treatment did not remove any sulfanilamide added to human milk.

Ten cc. of protein-free filtrate, prepared by adding one volume of 20 per cent trichloroacetic acid to one volume of milk and filtering, is pipetted into a 25 cc. volumetric flask. To this is added 4 cc. of 20 per cent copper sulfate and 4 cc. of a 20 per cent calcium hydroxide suspension. If the calcium hydroxide suspension has not been freshly prepared, more than 4 cc. may be necessary in order to make the contents of the flask alkaline. The contents are shaken frequently for one-half hour, diluted to 25 cc. and filtered. Five cc. of the filtrate (equivalent to 1 cc. of milk) plus 1 cc. of six normal hydrochloric acid are put into a test tube 25 by 200 mm., covered with a small beaker and placed in boiling water for thirty minutes. After

Eli Lilly & Co. furnished the sulfanilamide used in this work.  
From the University of Nebraska College of Medicine, Department of Biochemistry.

Dr. Sergius Morgulis showed continued interest and gave advice throughout the course of this work.

cooling, one drop of phenolphthalein is added and the hydrolyzed mixture is neutralized with concentrated sodium hydroxide solution. The liquid is then transferred to a 10 cc. volumetric flask and diluted to volume. Five cc. of this diluted material (equivalent to 0.5 cc. of milk) is pipetted into a 25 cc. test tube and the analysis for sulfanilamide is made as originally described by Marshall<sup>2</sup> for sulfanilamide in urine. To the 5 cc. of filtrate are added 5 cc. of water, 2 cc. of tenth normal hydrochloric acid, 5 cc. of 95 per cent ethyl alcohol, 1 cc. of 0.1 per cent sodium nitrite and 1 cc. of the dimethyl-alpha-naphthylamine reagent. It is not necessary to treat the standard with trichloroacetic acid, copper sulfate or calcium hydroxide. The trichloroacetic acid in the milk filtrate is decomposed on hydrolysis and does not affect the final color produced. The copper sulfate-calcium hydroxide treatment of the filtrate does not influence the color production.

CLINICAL RESULTS

In the lactating woman a study was made of the excretion of both sulfanilamide and the acetylated compound in the milk and urine.

The patients used in this report had been delivered of normal babies several days previously and had normal kidney function. During the period of the study the babies were placed on an artificial formula. The patients were given 4 Gm. of sulfanilamide in divided doses at 7, 8 and 9 a. m. For the next twenty-four hours no change was made in the diet or fluid intake. The urine was collected for twenty-four hours and the total amount of sulfanilamide and acetylsulfanilamide excreted in it was determined.<sup>2</sup> The milk was collected every four hours, the breasts being pumped dry, and determinations of the sulfanilamide and acetylsulfanilamide content were made for the twenty-four hour period. The entire amount of sulfanilamide administered was not excreted during that time but the amount left in the body was not sufficient to influence the results. Table shows the results obtained.

Excretion of sulfanilamide and acetylsulfanilamide in human milk.

On the chart and in the table it can be seen that the peak of excretion of conjugated sulfanilamide in milk occurs several hours later than the peak of excretion of free sulfanilamide in milk. Both these curves are similar in shape to the concentration of sulfanilamide in the blood as described by Marshall,<sup>2</sup> with the difference that in blood the peak of the concentration of the drug occurs several hours earlier than it does in the milk.

COMMENT

The concentration of sulfanilamide in human milk after the ingestion of a single large dose of the drug follows a course similar to that found by other workers for its concentration in blood.<sup>5</sup> The only difference is that the peak of concentration in milk seems to lag behind that in the blood by several hours. The concen-

tration of acetylsulfanilamide in milk has a similar concentration curve except that the peak of concentration occurs several hours later than the peak for free sulfanilamide. Analysis of separate samples of milk shows no tendency on the part of the breast tissue to concentrate the drug in the milk. In fact, from the evidence at hand it would seem that the concentration of the drug in the milk is directly dependent on the level in the blood and that when the blood level falls there is a similar fall in the level of sulfanilamide in the milk. This would seem to be accomplished by reabsorption of the drug into the blood from the milk, thus tending to prevent dangerous accumulation of the drug in the milk. This mechanism prevents nursing infants from ingesting harmful amounts of the drug from the milk.

A study of the figures for L. K. in the table shows that, while the patient secreted 428 cc. of milk during the twenty-four hour test period, this milk contained a total of only 17.2 mg. of free sulfanilamide and 23 mg. of acetylsulfanilamide, calculated as sulfanilamide. More than half the dose of sulfanilamide was excreted through the kidneys in the first twenty-four hours after administration. This is certainly an example of the general principle that noxious drugs are rarely secreted in the milk of nursing mothers in quantities sufficiently large to harm the nursing infant.

Theoretically, any nursing baby under 1 year of age will not take more than 1,200 cc. of milk a day. If the mother's blood level of sulfanilamide should be kept at 10 mg. per hundred cubic centimeters for the full twenty-four hours, the baby would not receive more than 0.12 Gm. of sulfanilamide and about 0.16 Gm. of acetylsulfanilamide. This dosage of the drug would not be harmful to any baby except one very allergic to sulfanilamide.

## SUMMARY

A method has been devised for the determination of sulfanilamide and acetylsulfanilamide.

From the limited series reported, it would seem that the amounts of sulfanilamide or acetylsulfanilamide excreted in human milk, when therapeutic doses are given to the lactating mother, is not ordinarily harmful to the normal nursing infant.

## ANEMIA DURING SULFANILAMIDE THERAPY

W. BARRY WOOD JR., M.D.

BALTIMORE

Acute anemia associated with the administration of sulfanilamide was first described by Harvey and Janeway.<sup>1</sup> Three cases were reported, and the accounts of two additional cases were later published by Kohn<sup>2</sup> and Willis.<sup>3</sup> Except for these few reports very little emphasis has been laid on the development of severe anemia as a complication of sulfanilamide therapy.

During the past year 522 patients have received sulfanilamide<sup>4</sup> in the Johns Hopkins Hospital. By far the commonest serious toxic complication observed in this series of cases has been the development of acute anemia. A special study of the cases in which anemia developed has been undertaken and the significant data obtained are reported in this paper.

## INCIDENCE

The incidence of acute anemia associated with sulfanilamide therapy is considerably higher than one might judge from the scarcity of reports in the literature. Among the 522 patients treated with sulfanilamide acute anemia developed in twenty-one, or 4 per cent. It is of interest that the incidence among children was higher than among adults. One hundred and forty-four children received the drug and acute anemia developed in twelve (8.3 per cent), whereas there were only nine cases of acute anemia among the 378 adults treated (2.4 per cent). Agranulocytosis was much less common than acute anemia, there having been but one case in the entire series.

## PREDISPOSING FACTORS

No definite predisposing factors were noted in the analysis of cases of acute anemia, but the following should be discussed briefly:

(a) *Type of Infection.*—The twenty-one patients in whom acute anemia developed were suffering from various types of both acute and chronic infections, as listed in table 1. No one form of infection seemed to predominate.

(b) *Fever.*—It may possibly be of significance that all twenty-one patients had fever (in most cases over 102 F.) at some time during the period of sulfanilamide therapy. No cases of acute anemia occurred among a

large group of afebrile patients who were given sulfanilamide for prophylactic reasons or because of chronic bacilluria. In one patient, a 2 months old infant, during a high fever severe anemia developed after three days of treatment, but later, when she was afebrile, anemia failed to develop when a second course of the drug was given. Whether or not the presence of fever predisposed to the development of anemia in these cases remains open to question.

(c) *Dosage.*—The patients in whom acute anemia developed did not receive on the average any larger doses of the drug than the other patients treated with sulfanilamide. The largest dose given was 0.2 Gm. per kilogram of body weight in twenty-four hours, whereas as much as 0.47 Gm. per kilogram has been given in other cases with apparently no harmful effects.

(d) *Concentration of Sulfanilamide in the Blood.*—The highest concentration of sulfanilamide encountered in the blood was 10.7 mg. per hundred cubic centimeters. Blood levels as high as 40 mg. have been observed among patients in whom anemia has not developed.

Chart 1.—Date of maximum anemia in cases of acute anemia associated with sulfanilamide therapy. Two cases were not charted because of insufficient data. Both hospital admissions of T. L. are included.

(e) *Acidosis.*<sup>5</sup>—The carbon dioxide combining power was within normal limits in all but two of the patients studied. The lowest value encountered was 33.4 volumes per cent. The carbon dioxide combining power, however, was not measured at sufficiently frequent intervals in any of the cases to rule out the possibility of a transient acidosis during the course of therapy.

## TIME RELATIONSHIP

In all cases of acute anemia in which hemoglobin measurements were made frequently, the fall in hemoglobin was shown to begin between twenty-four and seventy-two hours after the onset of treatment. The maximum anemia occurred most frequently on the fifth day, and in no case was it recorded before the third day or after the seventh day (chart 1). It should be emphasized that in the entire series of 522 cases in which sulfanilamide therapy was used no rapidly progressing anemias developed after the first week of therapy except when there was an obvious cause such as loss of blood at operation.

A second type of anemia observed occasionally during sulfanilamide therapy has been reported by Jennings and Southwell-Sander<sup>6</sup> and might be termed a "slow

4. The great majority of the patients were treated with sulfanilamide; a few received the closely related compound protosil (the disodium salt of 2'-azo-7'-acetyl-amino-1'-hydroxynaphthalene-3', 6' cases are reported through the courtesy of Drs. Edwards A. Park.

5. Jennings, G. H., and Southwell-Sander, G.: Anemia and Agranulocytosis During Sulfanilamide Therapy, *Lancet* **2**:898 (Oct. 16) 1937.

anemia." The fall in hemoglobin progressed slowly in their three cases, the maximum anemia occurring from two to four weeks after the start of treatment. My associates and I have observed eight similar cases of "slow anemia," but, since it is extremely difficult to determine in most instances whether the anemia is due to sulfanilamide or is secondary to a long standing infection, I have not included them in the present analysis.

#### NATURE OF ANEMIA

In their original publication, Harvey and Janeway described the acute anemia occurring during sulfanilamide treatment as a hemolytic anemia. Studies on the blood of their three patients indicated that there was rapid hemolysis associated with the fall in hemoglobin. Recently we have had the opportunity of following the entire course of a recurrent acute anemia which developed during a second course of sulfanilamide treatment. Because of the completeness of the data obtained, the case is reported in some detail:

#### REPORT OF CASE

T. L., a Negro chauffeur aged 36, first admitted to the Johns Hopkins Hospital March 15, 1937, complained of a severe sore throat. His general health had been excellent in the past. In 1922 he had had a peritonsillar abscess which required incision and drainage. Since childhood he had had frequent rather mild sore throats. Two days before admission to the hospital a cold in the head developed followed by a sore throat, which became progressively worse until he came to the hospital.

The clinical and laboratory examinations as well as the patient's course in the hospital during his first admission have been reported in detail by Harvey and Janeway (case 1) and need only be outlined briefly. The temperature was 104 F., pulse rate 110 and respiratory rate 40 per minute. The patient appeared acutely ill. No abnormalities were noted on physical examination except enlarged tonsils covered with flecks of yellowish exudate and tender lymph nodes palpable at the angles of the mandible. The blood was normal except for a leukocyte count of 19,000. Culture of material from the throat showed 95 per cent beta hemolytic streptococci.

Sulfanilamide therapy was begun on the first day and the patient received 21 Gm. of the drug over a period of five days. On the third day the throat infection appeared to be clearing and the temperature and white blood cell count had fallen to normal. The patient, however, complained of nausea and dizziness and, when two days later the temperature rose to 102.6 F., the drug was stopped promptly. On the seventh day it was noticed that the mucous membranes were pale and the scleras were jaundiced. Examination of the blood revealed a hemoglobin content of 30 per cent, a white blood cell count of 87,000 and changes in the blood smear indicative of increased activity of the bone marrow. The urine showed large amounts of urobilin but the serum bilirubin was not appreciably increased. The patient was given three transfusions during the next three days and recovery was rapid and uneventful. Just before discharge from the hospital he was given a test dose of 0.9 Gm. of sulfanilamide with no demonstrable effect on the blood.

March 6, 1938, nearly twelve months after his first admission, the patient was readmitted to the hospital with a severe sore throat of five days' duration. For two days he had had great difficulty in swallowing.

The temperature was 101.8 F., pulse rate 118 and respiratory rate 22. The patient appeared acutely ill and complained of great pain on swallowing. Again there were no abnormalities made out on physical examination except for tender enlarged cervical lymph nodes and inflamed tonsils covered with patches of white exudate. The tonsils were so swollen and edematous that they nearly met in the midline and threatened to close off the pharynx entirely. There was a slight swelling in the left peritonsillar region suggestive of an early peritonsillar abscess. Again there was a predominance of beta hemolytic streptococci in the throat culture.

As shown in chart 2,<sup>6</sup> examination of the blood revealed nothing remarkable except a white blood cell count of 18,900. The blood smear was normal. There was no immediate or twenty-four hour sickling and no increase in the fragility of the red blood cells. The icterus index was 7, examination of

† Maximum anemia on fifth day. Patient was given two transfusions but the drug was not discontinued until five days later.

the urine was negative for urobilin and the van den Bergh test showed no increase in serum bilirubin.

At the time of admission the question was at once raised as to the advisability of treating the patient with sulfanilamide, in view of his previous experience. At that time only one report of recurrent anemia during sulfanilamide therapy had appeared in the literature.<sup>3</sup> We had followed one patient, a 9 months old female infant, in whom anemia failed to develop

6. The laboratory studies were carried out by Dr. R. F. Howard and Mr. R. L. Sewell.

during a second course of sulfanilamide after the child had suffered a severe anemia with the first course. In addition, as already mentioned, the patient in question had been given a test dose of sulfanilamide at the end of his first hospital admission without any demonstrable effect on the blood. It was therefore quite uncertain whether on this occasion hemolytic anemia would develop if sulfanilamide were given. Because of the severity of the streptococcal infection of the tonsils it was finally decided to give sulfanilamide cautiously

globin could be detected in the urine at any time. The urine from the fourth to the eighth day was a dark amber and Dr. E. K. Marshall was able to recover a reddish pigment by ether extraction which became colorless when reduced with zinc and showed absorption bands in the same range as certain of the porphyrins. The pigment has not as yet been clearly identified.

COMMENT

From the data obtained in this case as well as in the other cases already reported, it is quite evident that the development of acute anemia during sulfanilamide therapy is associated with rapid hemolysis. The abrupt rise in serum bilirubin as shown by the van den Bergh test and icterus index, the presence of excessive amounts of bile pigments in the urine and the demonstration of free hemoglobin in the blood plasma all point conclusively to an active hemolytic process. Kohn<sup>2</sup> has reported an additional sign of rapid hemolysis, namely hemoglobinuria. However, we have been unable to demonstrate free hemoglobin in the urine of any of the twenty-one patients in the present series except in one case which was complicated by gross bleeding from a carcinoma of the bladder.

EARLY DIAGNOSIS

The early signs of acute anemia associated with administration of sulfanilamide are well illustrated by the foregoing case and may be summarized as follows:

- 1. Nausea and dizziness usually begin from twelve to twenty-four hours before the signs of anemia are detected.
- 2. Increased excretion of urobilin in the urine is often the first laboratory evidence of increased destruction of the blood.
- 3. There is an unexplained rise in temperature on the third to the fifth day of therapy.
- 4. There is a sudden drop in hemoglobin.
- 5. Hyperbilirubinemia and jaundice are present.

Chart 2.—Results of blood and urine studies in case of acute hemolytic anemia associated with sulfanilamide therapy.

and watch the blood with great care in order that the drug might be stopped immediately if signs of anemia should develop. Sulfanilamide was administered as shown in chart 2, a total of only 7.8 Gm. being given over a period of three days. The clinical response to the drug was dramatic. The temperature fell within twenty-four hours to 99.4 F. and the edema and inflammation in the throat subsided rapidly. The patient felt greatly improved on the third day, but in the afternoon he mentioned that he was slightly nauseated, and urobilin appeared in the urine. When the temperature rose to 100 F. on the following day and the hemoglobin, which was being checked every twelve hours, showed a slight drop, the sulfanilamide was stopped immediately. Fluids were forced to promote excretion of the drug through the kidneys and at the end of twenty-four hours the blood showed only a trace of sulfanilamide. In spite of the fact that the drug was stopped at the first signs of blood destruction, the anemia progressed rapidly during the next forty-eight hours, the hemoglobin finally falling to 40 per cent. The icterus index rose to 35, the van den Bergh reaction to 3.1 mg. per hundred cubic centimeters (indirect) and the patient became jaundiced and continued to excrete large quantities of urobilin in the urine. The reticulocyte count reached a maximum of 6.8 per cent on the fifth day. That the hemolytic process subsided as rapidly as it had begun is shown by the precipitous fall in serum bilirubin, which took place on the fifth and sixth days. The patient was given one transfusion of 500 cc. of citrated blood on the sixth day; thereafter he made an uneventful recovery. Blood serum drawn on the fifth day showed large amounts of free hemoglobin identified spectroscopically. No free hemo-

If every patient treated with sulfanilamide is carefully watched for the appearance of these signs, the diagnosis of acute hemolytic anemia can be made relatively early. It should be pointed out that even the earliest diagnosis may not prevent the development of a profound anemia. This is well illustrated by the case reported here, in which the anemia continued to progress rapidly in spite of the fact that the drug was stopped before the hemoglobin had dropped 10 per cent. Although the rapid fall in hemoglobin often cannot be

prevented by early diagnosis, it is only reasonable to suppose that the severity of the anemia can to some extent be controlled by early withdrawal of the drug.

#### RECURRENT ACUTE HEMOLYTIC ANEMIA

To date we know of five patients who have been given a second course of sulfanilamide in spite of the occurrence of acute anemia when they were first treated. In four of the five hemolytic anemia developed during the second course of therapy. The fifth patient escaped when treated a second time, but the absence of fever in this instance and the slightly smaller dose administered may have accounted for this exception. The data from these five cases are summarized in table 2 and serve to emphasize the danger of giving sulfanilamide to patients in whom acute hemolytic anemia has previously developed while under treatment with the drug.

#### PATHOGENESIS

Little is known about the pathogenesis of acute hemolytic anemia associated with sulfanilamide therapy. It is clear from studying the blood of patients suffering from this type of anemia that the drug acts either directly or indirectly on the red blood cells, causing hemolysis. There is no evidence that the anemia is in any way related to depression of the bone marrow, for in all the cases studied there have been signs of increased rather than of decreased hemopoiesis. However, no direct examinations of the bone marrow have been made. Thus far it has been impossible to reproduce the hemolysis by adding sulfanilamide to the blood *in vitro*. No sickle cell traits or increased fragility of the red blood cells have been detected in any of the cases. The Donath-Landsteiner test has consistently given negative results.

Acute anemia associated with sulfanilamide therapy must be classed as a drug idiosyncrasy, especially in view of the fact that the majority of patients who have once suffered an attack appear to be susceptible to recurrent attacks. The exact mechanism whereby the drug causes hemolysis must await further study of the blood of susceptible persons.

#### TREATMENT AND PROGNOSIS

The treatment of acute sulfanilamide anemia consists of two measures: (1) immediate withdrawal of the drug and (2) blood transfusion. That the first of these measures alone may not be effective, even when carried out early in the course of anemia, has already been emphasized. The response to blood transfusions has in all cases been satisfactory. No deaths from hemolytic anemia have been reported.

#### CONCLUSIONS

From the study of twenty-one cases of acute anemia associated with sulfanilamide therapy the following conclusions may be drawn relating to the management of patients under treatment:

1. The hemoglobin should be measured at daily intervals during the first week of treatment and once or twice a week thereafter as long as the treatment is continued. The urine should be examined frequently for urobilin during the first week, and all unexplained febrile reactions should be looked on with suspicion. The patient should be asked frequently about subjective symptoms such as nausea and dizziness, and jaundice should be carefully watched for.

2. At the first signs of the development of hemolytic anemia sulfanilamide should be withdrawn, fluids forced

and the patient's blood matched for transfusion. If the hemoglobin falls to dangerously low levels, repeated transfusions are indicated.

3. Patients who have once suffered from acute hemolytic anemia during sulfanilamide treatment should not again be given the drug.

#### SUMMARY

1. Twenty-one cases of acute anemia associated with the administration of sulfanilamide, in a series of 522 patients treated with the drug, were studied. The incidence was higher in children (8.3 per cent) than in adults (2.4 per cent). No definite predisposing factors were noted in an analysis of the twenty-one cases.

2. The earliest signs of the anemia appeared between twenty-four and seventy-two hours after the onset of treatment. The maximum anemia occurred usually on the fifth day, and in no case did it occur before the third or after the seventh day.

3. The anemia has been shown conclusively to be associated with acute hemolysis, but the pathogenesis is at present not known.

4. Four out of five patients in whom acute anemia had developed when first treated with sulfanilamide suffered recurrences when a second course of the drug was given.

5. The anemia is treated by the immediate withdrawal of sulfanilamide, the forcing of fluids and blood transfusions. There have been no deaths reported.

6. It is important that the hemoglobin be watched carefully during the first week of sulfanilamide therapy.

### *Clinical Notes, Suggestions and New Instruments*

#### RECOVERY FROM SUBACUTE INFECTIOUS ENDOCARDITIS FOLLOWING PRONTOSIL THERAPY

RALPH H. MAJOR, M.D., AND LEE H. LEGER, M.D.  
KANSAS CITY, KAN.

Recovery from subacute infectious endocarditis is of such uncommon occurrence that the account of such a case seems worthy of record.

*History.*—O. H., a Negress aged 39, who entered the University of Kansas Hospitals April 13, 1938, complained of chills and sweats. The family history was negative. In 1930 the patient was admitted to this hospital with tonsillitis and arthritis. At that time a tonsillectomy was performed. She remained in the hospital from April 20 to May 4. Examination of the patient showed, in addition to the arthritis, a systolic murmur at the apex and a diastolic murmur over the aortic area and down the left sternal border. The diagnosis at that time was acute rheumatic fever, chronic tonsillitis, aortic insufficiency and mitral insufficiency.

The patient has been followed in the outpatient department for the past eight years and there are repeated notes regarding the presence of mitral and aortic murmurs. On several occasions she has shown marked cardiac failure. One month before admission to the hospital the patient had an abortion, which was followed by chilly sensations and some fever. This persisted only two days, following which she felt perfectly well. One week before the present admission the patient began feeling ill and complained of chills and sweats every afternoon; she had been "up and down in bed" most of the past week.

*Examination.*—At the time of admission the patient was lying listlessly in bed with a temperature of 100.8 F. Examination of the eyes showed several small petechial hemorrhages in the conjunctiva of the left eye and also a few petechiae on the left

From the Department of Internal Medicine, University of Kansas School of Medicine.

check and on the left side of the neck. The fingertips were painful, and one splinter hemorrhage under the nail was seen on the right index finger. The heart was enlarged; there was a loud rough systolic murmur at the apex and a soft blowing diastolic murmur over the aortic area. The liver extended two fingerbreadths below the left costal margin. The spleen was palpable and definitely enlarged.

The laboratory examination showed red blood cells 3,940,000, white blood cells 17,300, hemoglobin 62 per cent. The urinalysis showed a specific gravity of 1.025, a trace of albumin and from 6 to 8 pus cells per high power field. A blood culture taken April 13 was positive for *Streptococcus viridans*. Blood cultures taken April 14 and 15 were likewise positive. The organism grew very readily and was typical in every respect. The sedimentation index of the blood April 13 was 30 with a vertical curve.

The patient on admission was started on prontosil<sup>1</sup> 10 cc. intramuscularly twice a day, and 10 grains (0.65 Gm.) of sulfanilamide four times a day. This therapy was continued until April 23, on which day the prontosil was given intravenously three times. The sulfanilamide by mouth was omitted because of the extreme nausea which had developed. The patient received transfusions of 500 cc. of citrated blood on April 19, 26 and 28. The patient received 10 cc. of prontosil three times a day from April 23 until April 25 and twice a day from April 26 until May 13, at which time treatment with prontosil was discontinued.

The patient's temperature, which had varied between normal and 103 F., did not go above normal on April 26 and from that time on remained normal. Blood cultures taken on April 23 and 27 and May 2, 7, 11, 17 and 20 were negative. The spleen was not palpable May 5. The blood count May 7 revealed red blood cells 4,160,000, white blood cells 7,200, hemoglobin 74 per cent. This was a marked change, particularly in the white blood cell count, which on April 22 was 23,000. The blood sedimentation curves were as follows: April 26: index 32, vertical curve; May 3: index 17, diagonal curve; May 14: index 7, horizontal curve.

Although the patient continued to be fever free, signs of cardiac failure became more and more evident. The patient's dyspnea increased, and marked edema and anasarca appeared. The patient died May 25, twenty-nine days after the temperature had become normal and twelve days after treatment with prontosil had been discontinued. Autopsy was performed two hours after death by Dr. Rae Richeson of the department of pathology.

**Autopsy.**—The anatomic diagnosis was chronic and subacute vegetative bacterial valvulitis of the mitral and aortic valves (healing bacterial endocarditis), acute and chronic myocarditis, hypertrophy and dilatation of the heart. The heart weighed 400 Gm. The mitral valve showed marked thickening and scarring, and at the apex of one of the valve cusps was a vegetation which appeared to be healing and was covered with a thin layer of scar tissue. The aortic valves were also thickened and wrinkled, and on their edges were several vegetations which appeared old and organizing. Both valves were incompetent. Microscopic sections of the mitral and aortic valves showed evidence of extensive healing. On the aortic valve deep beneath the healed surface were some clumps of gram-positive diplococci. Cultures taken from small excised portions of the mitral and aortic valves were sterile.

#### COMMENT

Recovery from subacute infectious endocarditis is admittedly very rare. Since the remarkable results reported in certain streptococcal infections with prontosil and sulfanilamide, it is obvious that this drug should be tried in the treatment of subacute endocarditis. Hussey<sup>2</sup> reports one probable case of endocarditis in which recovery occurred after the use of sulfanilamide. The diagnosis in this case would, however, seem to be open to doubt. In our case there is no question as to the diagnosis. The patient had a history of rheumatic fever and old mitral and aortic valve lesions, petechiae, splinter hemorrhages, tender

fingers, fever, enlargement of the spleen and three blood cultures positive for *Streptococcus viridans*. Necropsy showed the evidence of a recent endocarditis in the stage of healing and repair.

The question open to doubt is whether the cure was produced by prontosil or whether it was a spontaneous recovery. A review of the literature to March 1, 1938, comprising 309 articles, discloses no claims of a case of endocarditis cured with sulfanilamide. In 1925 the senior author<sup>3</sup> reported a case of subacute infectious endocarditis due to *Streptococcus viridans* but showing no embolic phenomena in which recovery occurred following the administration of intravenous gentian violet. Subsequent failures to influence this disease by the administration of gentian violet have led us to the conclusion that this was a case of spontaneous recovery, such as those reported by Oille, Graham and Detweiler,<sup>4</sup> which also showed no embolic phenomena.

There are, however, certain features of this case which suggest that prontosil acted as a curative agent. The fall in temperature, the disappearance of positive blood cultures, the change in the sedimentation curve, the disappearance of the enlarged spleen and the cessation of embolic phenomena, all following so closely the intravenous administration of prontosil, are highly suggestive. It is noteworthy that no change in the temperature occurred until prontosil was administered intravenously; also that the endocarditis was probably only of one month's duration and possibly only of one week's duration when therapy was instituted.

#### THROMBOPENIC PURPURA DUE TO FOOD ALLERGY

L. O. DUTTON, M.D., EL PASO, TEXAS

In January 1937 Squire and Madison<sup>1</sup> reported three cases of thrombopenic purpura that were found to be due to sensitization to food. These cases all conformed to the usual hematologic criteria for the diagnosis of the condition. All of the patients were relieved of their symptoms following the removal of the foods found to be the causative agents, and the symptoms returned on readdition of these foods to the diet. In view of the fact that many cases have been reported which showed thrombopenic purpura due to sensitization to drugs, and in view of the relationship shown by Squire and Madison between sensitization to certain foods and the thrombocyte level in the blood, it is evident that this etiologic possibility should be considered when these cases are encountered.

It is my purpose in this short communication to record another case in which food allergy was the etiologic factor in thrombopenic purpura.

#### REPORT OF CASE

**History.**—A. L. D., a white woman aged 59, was referred by Dr. Gottlieb Werley for blood study with the clinical diagnosis of purpura, probably due to an allergy to citrus fruits. The patient presented numerous ecchymotic spots distributed over the entire body. There were also innumerable petechial hemorrhages distributed over the forearms, thighs and legs. Ecchymoses had begun to appear about six years previously as occasional areas appearing on the limbs. There were free periods when there were no lesions. The bruises had increased in frequency and number until they were almost constantly present. It required about ten days for an area to clear after the hemorrhage appeared.

Ten days previous to the first visit there appeared numerous petechial hemorrhages over the limbs. This had never occurred before. For several days the number of petechiae increased. The petechiae followed the ingestion of a large quantity of citrus fruits while the patient was visiting in a citrus fruit raising community. The patient stated that she was not particularly fond of citrus fruits although she partook of one or the other of them frequently in small quantities. There were

1. Squire, T. L., and Madison, F. W.: Thrombocytopenic Purpura Due to Food Allergy, *J. Allergy* 8: 143 (Jan.) 1937.

1. Prontosil is the disodium salt of 4-sulfamido-phenyl-2'-azo-7'-acetyl-amino-1'-hydroxynaphthalene-3', 6' disulfonic acid.

2. Hussey, H. H.: Probable Bacterial Endocarditis Apparently Cured with Sulfanilamide, *M. Ann., District of Columbia* 6: 273-276 (Sept.) 1937.

no subjective complaints, and the usual daily routine was being carried out as usual. Five days after the appearance of the petechiae a severe epistaxis occurred, which subsided to a slow capillary bleeding from the nasal membrane.

The essential points in the past history were as follows:

Head: Nasal congestion for many years.

Cardiorespiratory system: Normal.

Gastrointestinal tract: A marked anorexia and a distressing sense of fullness after even very small meals.

Genito-urinary tract: A severe hemorrhage after an operation on the kidney twenty-seven years previously. The details of this operation were not known. One year before admission there had been an attack of pain and hemorrhage from one kidney attributed to a stone, although no stone was demonstrable by complete x-ray and cystoscopic examination.

The menses had begun at 18 years and the menopause occurred at 52. Otherwise the menses were normal.

Other past illnesses were typhoid thirty years before and severe hives in childhood. There had also occurred the usual diseases of childhood.

The family history was insignificant except that the mother and one sister had had severe headaches for many years.

Other items in the past history were negative.

*Examination.*—The physical examination was negative except for the cutaneous lesions described. The abdominal wall was rather obese and satisfactory palpation of the spleen could not be accomplished.

Examination of the blood showed total white blood cells 5,600, total red blood cells 3,900,000, hemoglobin 12.5 Gm. per hundred cubic centimeters, neutrophil polymorphonuclear leukocytes 63 per cent, immature neutrophils 3 per cent, lymphocytes 28 per cent, eosinophils 5 per cent and basophils 4 per cent. There was slight irregularity in the size and shape of the red blood cells. In the stained smears only an infrequent platelet was seen. Direct enumeration of the platelets showed 60,000. There was no retraction of the clot after several days' standing.

The urine contained a trace of albumin, many pus cells and a few red blood cells.

Cutaneous reactions to food were negative. Intracutaneous reactions were definitely positive to orange, lemon, shrimp, avocado, apple, milk, rye, cheese and cottonseed. A number of other borderline reactions were obtained.

Leukopenic indexes were as follows: milk negative, wheat negative, egg borderline and orange positive.

A diagnosis was made of thrombopenic purpura, probably due to allergy to citrus fruits.

*Progress.*—The course of the condition confirmed the diagnosis. A diet was prescribed in which the foods giving positive reactions were omitted. No new ecchymotic areas appeared, although previously there were several new ones each day. Ten days after the diet was started the skin was practically clear. On this day the leukopenic index was done for orange juice. As already noted, the result was positive. The next day there were two large ecchymotic areas on the forearm. Before this test was done the platelet count had risen to 240,000 and the clot retraction time was normal. On the day after the test the platelet count was 100,000. After another month there had appeared no new lesions. Small amounts of citrus fruits were then added to the diet. After three days several small ecchymotic areas appeared on the limbs. The fruits were again removed from the diet and after four months there has been no return of the symptoms.

It is interesting to note that the anorexia and the sense of fullness after meals have disappeared. The platelet count is now 385,000. The remainder of the blood count is normal. The patient feels in better general health than she has for several years past.

#### COMMENT

Two thoughts seem to be indicated by this and other similar cases. First, the obvious one, that at least an unknown percentage of persons suffering from this disease might be relieved by a much simpler procedure than radical splenectomy. Certainly the results with this case were much more striking than those obtained by the more tedious and disappointing general therapy employed in the past.

Second, it is amazing that a shock organ could be so narrowly limited that only the cells responsible for the platelet formation in the bone marrow could be affected by an allergen or, on the other hand, that an allergic reaction should result in an abnormal function of the spleen (destruction of red blood cells).

#### SUMMARY

A case of thrombopenic purpura has been successfully and easily controlled by the removal from the diet of foods to which the patient was allergic.

### CANCER OF THE CERVIX UTERI: RECOGNITION OF EARLY MANIFESTATIONS

CLINICAL LECTURE AT SAN FRANCISCO  
SESSION

KARL H. MARTZLOFF, M.D.

PORTLAND, ORE.

It is one thing to recognize cancer early, i. e. when it is first seen, but it is quite another to recognize early cancer, i. e. cancer in its incipience. It is to the recognition of early cancer that I shall confine my remarks.

When one considers that genital carcinoma comprises about 2 per cent of cancers in the male while it forms about 27 per cent of cancers in the female, its comparative importance is at once manifest. In general it may be said that of all women suffering from cancer about one third are afflicted with uterine cancer. Of these about 80 per cent have cancer originating in the cervix uteri.

The foregoing remarks would represent only statistical repetitions did they not develop the startling revelation that one of the organs most commonly involved in cancer in women is situated suitably for direct visualization, palpation and instrumentation as is no other human organ which has an equally high incidence of cancer. The obvious conclusion follows that the unequivocal diagnosis of established cancer of the vaginal portion of the cervix uteri generally is a simple matter and should follow closely on the first examination.

Equally important is it that so many patients who possess a so-called suspicious-appearing cervix, whatever that may be, should not be terrified by the fear of cancer and subjected to a long series of office treatments for the time-tattered, hysterical and questionable excuse of cancer prophylaxis, when it is possible to establish practically beyond peradventure the presence or absence of anything suggestive of cancer.

#### EARLY VISIBLE CANCER

This brings up at once the problem of recognizing the early manifestations of cervical cancers. Fortunately the majority of such cancers occur on the portion in the region about the external os. The primary prerequisites for their recognition are threefold: adequate exposure of the cervix, adequate illumination and deliberate, thoughtful inspection. There is little doubt that, if all physicians would observe these elementary

Read in the Surgical Division of the General Scientific Meetings at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 14, 1938.

requirements, most cervical cancers would be suspected on the first examination, while they were still comparatively early yet advanced far enough to produce slight tumefaction, a small ulcer or some other superficial change outside the normal variation, although symptoms might be entirely lacking. One would then have the desirable combination of early recognition of comparatively early cancer.

In speaking of early cancer of the cervix it may be helpful merely for the purpose of clarifying the discussion to segregate early cancer arbitrarily into two classes: cancer in that phase in which, while still small, it is clinically recognizable, and cancer in an earlier phase, in which one is not ordinarily prepared to recognize it and the gross physical aspect of the tumor is not so apparent. For descriptive purposes the latter may be considered as hidden, covert or latent cancer.

Clinically recognizable early cancer of the vaginal portion of the cervix, as physicians have been taught to recognize it, usually presents itself as a red, firm, irregular, somewhat elevated circumscribed process, situated ordinarily in the neighborhood of the external os. It generally bleeds readily on light manipulation

adjoining normal-appearing tissue. The block so obtained should be rectangular or nearly so, as shown in the accompanying illustration, and should immediately be fixed in solution of formaldehyde or other suitable fixing solution. If the material is obtained and prepared in this way, when it is ready for microsectioning there is little doubt about the direction in which the block should be cut. Minute fragments of tissue, wedge-shaped pieces of tissue and material obtained by scooping out tissue with the endothermy loop may be entirely unsatisfactory. The advisability of curetting the surface of the process as has been recommended is also a dubious procedure. Ordinarily there can be little excuse for such haphazard methods, when the lesion is small, circumscribed and primarily a diagnostic problem.

When the area under suspicion is more diffuse or located on a cervix that otherwise merits some form of operative correction, an amputation or a Sturmdorf procedure combined with amputation, as described by Te Linde,<sup>1</sup> is a convenient method of simultaneously obtaining material for biopsy and correcting a local pathologic condition. Whether the scalpel or the endothermy current is employed for this purpose probably matters little. However, if the latter is used one should allow for destruction by heat along the margins, where the fragment of tissue becomes unsuitable for histologic study. When a tumor is large and its character obvious, naturally observance of such minutiae is not essential.

One must of course recognize that early visible cancer probably has no distinctive gross appearance which permits its exact clinical diagnosis. Heretical as it may sound, it is also probably true that more advanced cancer possesses no distinctive or grossly pathognostic appearance. Its clinical recognition rests on the fortuitous circumstance that most ulcerating, indurated tumors of the portio are cancer.

Aside from such relatively rare lesions as those of syphilis, tuberculosis and venereal granuloma, all of which may grossly simulate cancer, the lesion which according to my experience is most commonly suspected of being an early cancer is the vermilion zone so commonly observed about the external os. This, generally referred to as an "erosion" or "ulceration," has a well marked tendency to bleed when complicated by vaginal inflammation, which renders the red surface especially susceptible to slight trauma, with the production of minute bleeding points (erosions). Generally, however, the circumstrial vermilion zone does not bleed and does not partake of the nature of erosion or ulcer.

The differentiation of a circumstrial vermilion zone of altered epithelization from an established cancer of similar size should ordinarily not be difficult. The former may be relatively smooth and flat or it may possess a fine irregularity giving it a finely granular appearance. It does not, however, appreciably change the gross contour of the cervix. If it involves both lips of the cervix, as it often does, it has its greatest expanse on the anterior and posterior lips, with narrow lateral connecting zones of red. On palpation with a sound the surfaces are found to be elastic, and under magnification cervical glands are visible pouring forth their watery secretion onto an intact, red and glistening mucosa.

Schematic representation of the method of obtaining material for histologic study. A represents a suspicious area on the anterior lip of the cervix uteri, with the dark lines indicating the direction of incisions for removal; A', the shape of the excised block of tissue, and B, a larger suspicious area, which in some cases may advantageously be removed by a cone-shaped enucleation of the endocervix, together with a portion of the portio, as indicated by the circularly dotted line.

with a soft cotton pledget and on palpation may feel indurated, although induration as a highly diagnostic sign has probably been greatly overemphasized. It is a lesion that should at once arouse one's suspicion as to its malignant character, and to discover it no apparatus is necessary that cannot be found in the office of any qualified physician. The obtaining of tissue for histologic examination without undue delay is imperative, so that one's diagnosis may be unequivocally established and treatment advised.

The obtaining of biopsy material from such a suspicious area on the vaginal portion of the cervix is in itself so important a matter that it cannot be overstressed. It may sound trite to say that material for biopsy must contain cancer before cancer can be revealed under the microscope. Most pathologists can testify to personal experience with tissue submitted to them from cancer-afflicted patients which either showed no cancer or was of debatable character while full-blown carcinoma existed a few millimeters from the site of the specimen. Tissue removed from a small circumscribed area suggestive of cancer should include both material from the suspicious area and a generous amount of

1. Te Linde, R. W.: Amputation of the Cervix with Application of the Sturmdorf Flap Principle, *Surg., Gynec. & Obst.* 43:513 (Oct.) 1926.

A small carcinoma on the surface of the portio does not have as perfect a circumstantial distribution as the common vermilion zone does, and ordinarily it is elevated, so that it alters the contour of the cervix. Its color generally offers a distinct contrast to the surrounding mucosa, while its surface is generally irregular and may show the opening of cervical glands. Palpation of the tumor with a sound reveals the irregularity previously noted and a lack of elasticity, and if there is beginning degeneration of the tumor the sound can be pushed with little force into the substance of the tumor, which then bleeds readily.

A small cancer with ulceration can so simulate a benign, nonspecific, inflammatory process of the cervix, while a benign process when complicated by induration and bleeding can so mimic cancer, that their gross differentiation may be impossible. However, such instances have so far been relatively uncommon.

Summarily, then, early cancer of the vaginal portion of the cervix that is clinically recognizable, as ordinarily encountered, presents a gross appearance which shows sufficient deviation from the normal to arouse suspicion. Obviously its true nature may not be recognized. Nevertheless, thoughtful appraisal of the lesion on the first examination should arouse sufficient concern to stimulate the proper removal of tissue for histologic study.

#### COVERT CANCER

I come now to a consideration of those processes on the vaginal portion of the cervix which, though their appearance does not correspond to the customary gross appearance of cancer, may represent an early phase of malignant change, i. e. covert cancer. Until comparatively recently such processes have been detected accidentally, on laboratory examination and have been unrecognized clinically as either potential or bona fide early nonulcerating cancer.

The ability to recognize clinically such processes represents a sort of cancer utopia which has probably been the dream of every physician at some stage of his medical career and is still the goal of many students of cancer.

The question is Have physicians reached this goal? The attempt has been made to bridge the hiatus between the phase of early tumefaction and ulceration of cancer and the antecedent covert stage, in which these changes have not occurred.

Presumably cancer of the portio vaginalis cervicis in its incipience passes through a stage in which the cells of the stratified epithelium in a localized area possess all the histologic earmarks of cancer but lack the property of invasion. I prefer to term this carcinomatoid process, limited to the normal boundaries of the epithelial zone before it has proved its destructive ability, probable beginning cervical cancer, because the expression carries a connotation of doubt. Such processes are also designated superficial cancer, cancer in situ, Bowen's disease, and carcinoid change. The term "precancerous" if ever permissible might conceivably also be used. The word, however, has such a definitive connotation that, with our present limited knowledge of cancer, it is doubtful that it can justifiably be employed.

Laying aside all theoretic considerations, one cannot say positively whether the ultimate fate of such suspicious lesions will be one of steady progression to invasion and full-blown malignancy or whether there may occur a process of regression and restitution to normal.

Similar epithelial changes are occasionally found at the periphery of bona fide cancers, and it is therefore necessary when the histologic picture of probable beginning cancer is seen to make certain that the material has not come from the margin of a full-blown malignant process.

Attention has been focused on these controversial areas of probable beginning cancer by the efforts of Hinselmann<sup>2</sup> and of Schiller.<sup>3</sup>

In the opinion of some authorities it is now possible to recognize clinically such early manifestations of presumptive cancer before the process of ulceration and prior, consequently, to the production of abnormal vaginal discharge, which is dependent on this change. The clinical methods designed to bring to one's attention areas of early covert cancer are limited in their application to the vaginal portion of the cervix uteri. The iodine test was proposed by Schiller, while Hinselmann advocated observation of the cervix under magnification with a suitably mounted binocular dissecting prism, which he has termed a colposcope.

The rationale underlying the iodine test of the epithelium of the vaginal portion of the cervix as proposed by Schiller is based on the observation of Warburg that cancer cells possess a higher sugar metabolism (glycolysis) than normal epithelium and the observation by Lahm, Schiller and others that cancerous epithelium usually shows an absence of glycogen. Since it has been shown by Langhans that iodine reacts with glycogen in living tissue the iodine test has been applied clinically to reveal areas possessing or lacking glycogen. The test, which has been given rather general use, is done simply by applying iodine in the form of Gram's<sup>4</sup> iodine solution to the cervix, which has been cleansed of its secretion. Normal mucosa assumes a mahogany brown color of varying intensity after from five to ten seconds of constant application. The iodine solution should be comparatively fresh.

#### THE COLPOSCOPE

The colposcope was devised by Hinselmann as a result of his observation of two large areas of leukoplakia (white plaques) on the vaginal portion of the cervix. Histologically these areas showed the cellular changes ascribed to cancer (mitoses, irregularity in size, shape, relationship and staining reaction of the cells) but they were limited to the anatomic confines of the epithelial zone, i. e. invasion was lacking. On the basis of this observation and a few earlier observations by von Franqué and others, which I<sup>5</sup> have discussed elsewhere, it appeared reasonable to infer that leukoplakia offered a starting point for cancer. Indeed, it has long been held by von Franqué<sup>6</sup> that cancer of the portio probably manifests itself first as a leukoplakic change and conversely that certain leukoplakic plaques are

4. Confusion exists regarding the type of iodine solution advised by Schiller. Since he referred to Lugol's solution in his original communication, it has been inferred by some workers that Lugol's solution as defined in the U. S. Pharmacopeia (compound solution of iodine U. S. P.) was meant. Schiller's reference, however, was to Lugol's solution as used for bacterial stain, which is the equivalent of our Gram's iodine solution (iodine 1 part, potassium iodide 2 parts, water 300).

6. von Franqué, O.: Leukoplakie und präcanceröse Veränderung des Plattenepithels, Zentralbl. f. Gynäk. 51: 898 (April 9) 1927.

destined eventually to become cancers. It therefore appeared logical to attempt to recognize these changes in their incipience, when they might be so small as to escape observation by the unaided eye. The magnification of from 10 to 15 diameters which the colposcope provides is designed to make such recognition possible and also to permit study of lesions other than leukoplakia.

Study of the cervix under magnification is interesting and informative if one controls one's observations with histologic studies. One learns that the cervix generally has a slight but definite pulsation synchronous with the heart beat; that cervical glands may open onto the portio 1 or 2 cm. from the external os through a normal stratified epithelium, which is bathed by their intermittent, crystal-clear secretion, and that glandular openings commonly occur also in the circumstrial vermilion zone and may have there small yellowish gray plugs simulating leukoplakia. Also it is not uncommon to note at the transition zone, where the pale pink of the normal stratified epithelium meets the bright red of the thin epithelium of the vermilion zone, areas where the epithelium is pale gray, almost white. Minute bleeding points (erosions) and small ulcers can be readily identified, as can also other more major deviations from the normal.

#### RESULTS OF TESTS

The question naturally arises as to how valuable these two methods are for the recognition of incipient cancer when compared with ordinary methods of careful inspection.

My experience with these methods now extends over approximately seven and one-half years. Unquestionably the iodine test is not specific for cancer or for areas of so-called probable beginning cancer. Schiller originally pointed out some of the pitfalls in this test but felt that nonstaining areas are often though not always cancerous. According to my experience the overwhelming majority of unstained areas, including areas of leukoplakia, show no histologic evidence suggestive of probable beginning cancer. Small epithelial gland plugs, vermilion areas, a proportion of superficially situated nabothian follicle cysts, areas of epithelial loss, either when superficial or, if complete, apparently when fibrin covers the base of the ulcer, epithelium involved in an underlying inflammatory process and particles of adherent inspissated secretion, together with other unexplained areas, fail to stain with the iodine. It follows that if areas that do not stain with iodine are not interpreted with due reserve they lead to endless confusion and alarm for the physician and unnecessary biopsy, cervical tinkering and hysteria for the patient.

Up to the present time I have not discovered a histologically proved area of probable beginning cancer with the iodine test, nor has the test proved to be of any more assistance than careful inspection with the unaided eye.

The altered epithelium that does not stain with iodine which occurs at the periphery of some established carcinomas has, as in Henriksen's case,<sup>7</sup> occasionally led to the suspicion and recognition of a cancer. So far, however, in most of such published instances<sup>8</sup> there

was a history of bleeding and an ulcerating cancer was present which should have been suspected from the beginning. It is, I believe, permissible to conclude that in its general application a test as unspecific as the negative iodine reaction is likely to be more confusing than it is to be helpful. Certainly, as I have noted elsewhere,<sup>9</sup> the test is not pathognomonic of a malignant condition, though it may possibly be a signal which calls for further study.

The colposcope, since it facilitates visual observation of the cervix uteri, would naturally appear to answer an unfulfilled need and to fall into the category of nasal and aural speculums, the proctoscope and the cystoscope. However, the corollary is not as apt as it sounds, for from the standpoint of the profession at large it has several drawbacks which probably will prevent its general adoption. These include the expense of the instrument, the time necessary to make a careful study and the need of extended experience to interpret correctly what one sees. The need of extended experience makes it necessary for the clinician to use the instrument regularly and to correlate the colposcopic appearance of the cervix with the histologic picture of the area in question. This requires frequent biopsies and study of the tissue by the clinician himself. The obtaining of tissue for biopsy takes the method out of the realm of simple office procedure, for if an area is sufficiently abnormal in appearance to warrant removal of tissue, removal should be carried out as described earlier in my discussion. An inadequate specimen for biopsy is probably worse than none, for it frequently makes it impossible for the pathologist to arrive at a correct interpretation. If cancer is present and the specimen does not contain any of it the patient's welfare is unjustifiably jeopardized.

However, I believe that the colposcope is a fundamental contribution to methods of visual examination of the vaginal portion of the cervix uteri. While I use it as a routine, it has been of essential value in only a few instances. So far I have discovered with it neither areas of unmistakable probable beginning cancer nor any small cancerous ulcers (established cancer) which I could not detect with the unaided eye on careful methodical examination. It is important to appreciate fully that the gross appearance of the small lesion of early established cancer, as pointed out by Hinselmann,<sup>10</sup> is not sufficiently characteristic to permit its differentiation from other nonmalignant lesions solely on the basis of its appearance through the colposcope.

#### EXPERIENCE OF VARIOUS WRITERS

A review of the more recent literature reveals a decided division of opinion, the details of which cannot be discussed here. Of fundamental importance, however, are the following observations: 1. Claims that leukoplakia of the cervix uteri is a precursor of cancer<sup>10</sup> lack confirmation at this time.<sup>11</sup> 2. Many of the histologic diagnoses of cancer made by Hinselmann have not been confirmed by disinterested pathologists to whom sections were submitted,<sup>12</sup> and there is no proof

at this time, as has been claimed,<sup>13</sup> that 20 per cent of areas of leukoplakia that are studied are carcinomatous. 3. Some of the cases reported to show the value of the colposcope for revealing an otherwise unrecognizable early cancer are reasonably debatable from the standpoint of their acceptability. If, for example, cancer is present it may be impossible to ascertain from the case report which part of the gross lesion showed cancer,<sup>14</sup> and, in fact, the proof of cancer may not be clear.<sup>15</sup> In the case reported by Leip and Otto,<sup>16</sup> in which leukoplakia presumably of twelve years' standing under constant observation underwent bona fide cancerous change, the patient in question was not seen by the authors until a few months prior to the time of her operation, and two years prior to this her cervix had been considered suggestive of cancer and biopsy had been advised on the basis of a speculum examination without a colposcope. 4. The infrequency with which cancer is found on routine prophylactic examination is evident from the experience of Hinselmann and Köhler.<sup>17</sup> These authors examined 1,133 women in three and one third years in the municipal woman's clinic of Altona. These women represented a special group who were without other complaint and either sought examination for cancer prophylaxis (sixty-eight instances) or had been referred by other physicians for this particular type of examination because of a "suspicious" cervix. Sixteen women (1.4 per cent) of this entire highly selective group showed histologic evidence of so-called probable beginning cancer. Obviously no such incidence would occur in an unselected group of women who were similarly examined.

## COMMENT

One cannot escape the feeling that there is considerable partisanship and bias on the part of the proponents of the colposcope. In fact one sees the question raised, in some of the discussions, of the advisability of enacting legislation compelling physicians who examine patients under the existing German sickness insurance plans to use the colposcope in all vaginal examinations.

The impression is unescapable that for the present the recognition of cancer of the cervix uteri in its early stages still rests on painstaking visualization and inspection and proper obtainment from unusual appearing areas of tissue for microscopic examination. To await the appearance of a large ulcer formation, obvious induration or a cauliflower-like tumefaction such as that described in textbooks before clinically suspecting cancer is like preparing for sea after the ship has sailed.

This critical evaluation of methods more or less recently popularized for the apparent simplification and ready determination of early cervical cancer should not be construed as unfriendly criticism. However, as noted before, on the basis of a fairly long and appreciable experience I believe that these methods possess greater limitations than is ordinarily ascribed to them. If these restrictions are appreciated, one will not be discouraged by finding little where much was anticipated.

## Council on Industrial Health

### ETIOLOGY OF PNEUMOCONIOSIS

LEROY U. GARDNER, M.D.

SARANAC LAKE, N. Y.

*This paper is one of a series on pneumoconiosis prepared at the request of the Council on Industrial Health. The succeeding articles will be published when available.—Ed.*

Although the term pneumoconiosis was not introduced until the nineteenth century, clinical symptoms were naturally enough associated with the inhalation of dust in occupation by the earliest medical writers. In the Renaissance both physicians and mining engineers were well aware of the fact that the metal miner suffered from shortness of breath and died prematurely, and anatomists had described "heaps of sand" in the lungs of stone cutters which grated on their knives. They called the condition phthisis, their term for any chronic disease of the lungs which was associated with emaciation and expectoration. While most of the various conditions originally known by this name were differentiated and fully described in the eighteenth and nineteenth centuries, it was not until 1902 that the role of inhaled dust began to be understood. In that year an English departmental committee, of which Dr. J. S. Haldane was the outstanding member, pointed out that the phthisis from which the Cornish tin miners suffered was different from ordinary tuberculosis. They concluded that "the primary injury of the lungs is due solely to the inhalation of stone dust but that this injury, while it is apparently capable of gradually producing by itself great impairment of respiratory functions . . . also predisposes enormously to tuberculosis of the lungs, so that a large proportion of the miners die from tubercular phthisis."

A few years later, in 1915, Collis<sup>1</sup> demonstrated that not all kinds of dust had the same effect. His statistical analyses of morbidity and mortality in workmen in various dusty trades indicated most clearly that exposure only to free silica dust was particularly dangerous. Such exposure caused disability with ultimate death from tuberculosis at an age period later than occurred in the rest of the population. Inhalation of silica combined as silicates or of nonsiliceous dusts had no such effects. Collis felt very strongly that the free silica particles did not injure the lungs by virtue of their hardness and sharpness because other particles with the same properties failed to do so, but he could offer no other explanation. In 1922 Gye, Kettle and Purdy<sup>2</sup> demonstrated that colloidal silica is toxic for rabbits and suggested that crystalline silica is dissolved in the body to produce the toxic colloid. These contributions of Collis and of Gye, Kettle and Purdy still dominate modern concepts of pneumoconiosis.

Clinical research in South Africa under the leadership of Watkins-Pitchford and Irvine clarified the relationships existing between the reaction to inhaled silica and tuberculous infection. By employing the method of serial roentgenography over long periods of time and checking their observations with post-

mortem examinations these observers have probably contributed more than any other group to a sound understanding of the pathogenesis and pathology of silicosis. Their work established the dual relationship existing between the infectious process tuberculosis and silicotic fibrosis. The infection may on the one hand remain latent and exert only an etiologic effect in modifying the amount and form of the reaction to silica dust; on the other it may itself develop in active but unusually chronic form as a result of the preestablished silicosis.

Until 1924 Collis's dictum that only free silica is a cause of pulmonary fibrosis remained unchallenged. In that year Cooke<sup>3</sup> reported a case in which inhaled asbestos was incriminated; other cases were soon discovered and today asbestosis is everywhere recognized as a second form of pneumoconiosis characterized by fibrosis. The disease can apparently be produced by the prolonged inhalation of any of the five different silicates known as asbestos. This form of pneumoconiosis does not seem to predispose to tuberculosis to the same degree as silicosis. Although English authorities believe that it has considerable effect, American experience has failed to reveal an excess of tuberculosis among asbestos workers.

A few years later Badham<sup>4</sup> reported peculiar conditions found on roentgen examination in a large group of gold miners in Western Australia. These men had been exposed to a dust containing a small amount of quartz mixed with a silicate of magnesium known as rhodonite. Since Badham's films bore a certain resemblance to those showing asbestosis and to those of men exposed to various other silicate dusts, he proposed the term "silicatosis" to describe all these conditions. His proposal has not been generally accepted as proof that the silicates as a class can produce fibrosis.

Today Collis's clearly defined concepts of pneumoconiosis are becoming confused again because enthusiastic observers in many fields are drawing deductions without sufficient knowledge of the problem as a whole. Roentgenologists are too ready to ascribe any abnormal shadow in the film of a workman to some dust which he may have inhaled. General pathologists have concluded that the mere presence of a certain mineral in a pulmonary lesion is *ipso facto* proof that this dust was the cause of the reaction. Experimental pathologists with high powered microscopes have searched the early reactions to inhaled dusts and drawn sweeping conclusions as to the potentialities of this or that mineral to cause fibrosis. Petrologists and chemists are performing test tube experiments which prove that some silicate is more soluble in water than quartz, deducing from the solubility hypothesis that it must therefore be a more potent irritant than quartz. Clinicians, who see only the disabled silicotic patient with advanced lesions, often complicated by tuberculosis, are insisting that only such conditions represent the true picture of silicosis.

Such intensive research on the different aspects of the problem is yielding valuable information, but theoretical knowledge is not yet sufficiently advanced to permit an evaluation of a hazard by mere analysis of dust or rock. At the present time the detailed study of the workman and his industrial environment still

constitutes the only certain method of establishing the existence of a dust hazard. Such investigations are profitably based on the experience of the Miners' Phthisis Prevention Committee in South Africa. They should include the following:

1. The occupational history of all employees should cover the entire industrial life of every workman. It should include the names of each employer, the kind of job, an estimate of the type and quantity of dust encountered and the approximate dates of each position held. The information is apt to be recalled most readily in reverse chronological order.

2. Roentgenologic examination of the chest constitutes the most important source of information as to the presence of abnormal changes in the lungs. For the detection of advanced lesions almost any quality of roentgenogram on film or paper will suffice; to discover early changes the best stereoroentgenograms are none too good. The interpretation of the films presupposes a thorough knowledge of the normal pulmonary patterns, a familiarity with the shadows of infectious lesions, and judgment unbiased by the knowledge that the subject may have been exposed to considerable dust.

3. Physical examination of the chest is of equal significance. In many cases in which films may reveal widespread pneumoconiosis, even of a silicotic type, the physical signs will be very slight, but this paradox in itself is significant. Complicating infections are usually productive of characteristic signs but they are often less obvious than in cases of simple infection. Only by physical examination is it possible to evaluate the effect of the pulmonary condition and determine whether disability exists.

To be most profitable, such examinations should be repeated at intervals, annually if possible and on infected individuals as often as the examining physician deems necessary. By serial reexamination of a considerable group it is possible to obtain an idea of the pathogenesis of a pneumoconiosis, its rate of development and its extent and probable outcome. Isolated examinations, not repeated, demonstrate the prevalence of abnormal changes in the lungs of the workmen. Little information as to evolution of disease can be obtained for the conditions of exposure in the present, and previous employment varies with the individual workman.

4. Postmortem examination of the lungs should be made as frequently as possible. Careful gross and histologic study of the pulmonary lesions constitutes the best guide to the interpretation of the shadows which are cast on a roentgenogram. Chemical and petrographic analysis of the lungs determine the amount and character of the inhaled mineral dust. The larger the number of such postmortem examinations the greater the likelihood of formulating a true concept of the disease arising from the dust under investigation. One or two isolated examinations may only obscure the picture because of previous exposures to other dusts not accounted for in the occupational history.

5. A detailed study of the industrial environment includes a chemical and petrographic analysis of the raw materials, in the case of a mine of the ore and the rock being worked, of a grinding operation of the wheels and the implements ground, and so on. But it should not be assumed that the composition of the raw materials will necessarily correspond with that of the dust created by manipulating them. It will be shown later that the free silica content of the rock may greatly exceed that of the dust liberated from it. Likewise, samples of dust settled on rafters do not necessarily contain the same proportion of silica as the dust suspended in the atmosphere. Analysis of air-floating material at the breathing level constitutes the only accurate measure of the dangerous minerals that a workman is likely to inhale. The relative amounts of silica and all other minerals should be determined because of mutual interactions which may reduce the concentration of the silica or modify its effects on the body. Not only the kind but

4. Badham, C.: Notes on a Fine Type of Fibrous Pneumoconiosis Produced by Silicates and Other Minerals, Report of Director-General of Public Health (New South Wales) for year ended Dec. 31, 1927, Sydney, Australia, Government Printing Office, 1929.

the quantity of the atmospheric dust must be measured. In the United States the Greenburg-Smith impinger apparatus is the standard, and the results are expressed in millions of particles per cubic foot of air. Other instruments, such as the Kotze konimeter used in South Africa, the Owens jet counter in Great Britain and the Bausch and Lomb dust counter in this country, give equally satisfactory results but ones which are not reciprocally translatable.

Such determinations must be made in all the various parts of the plant or mine where men are at work, for both the quantity and the quality of the dust vary from the point of generation to others more remote. Furthermore, repeated sampling is essential to establish the amount of dust that the men inhale in any operation. Local variations in the velocity of air, humidity and general ventilation all affect the picture. The average amount of atmospheric dust must be based on many samples taken over periods of months or years.

By correlating the results obtained from such a study it is possible to evaluate the effects of the particular dust under the conditions existing in a particular plant. The results can be applied to another industry only when it has been proved that the composition and concentrations of dust in the second plant are similar. Only then is it safe to assume that the mass effects will be comparable. Individual variations will always be discovered because certain persons are more susceptible to dust by virtue of associated pulmonary infections. Sometimes the picture in the whole group will be altered because of a high local incidence of tuberculosis.

#### EXPERIMENTAL INVESTIGATIONS

Since so many industrial processes involve creation of dust and since a detailed study of each one of them would be both time consuming and expensive, there is reason to seek accessory sources of information. Animal experimentation has demonstrated its value as such a source. While many experiments have failed to reproduce disease processes entirely comparable to those observed in human beings, they have demonstrated fundamental principles which govern the reaction of living tissues to various kinds of mineral particles.

The experimental pathologist may test the action of a given dust by the inhalation method, which purports to create an atmospheric environment comparable to that in industry. This method is time consuming, expensive and fraught with technical difficulties, and frequently it fails to produce the anticipated results. The experimenter sets up rigidly controlled conditions, which are kept as constant as possible over periods of months or years; in industry conditions are rarely constant but continue to change from hour to hour. With pure mineral dusts experimental inhalation generally produces a pneumoconiosis comparable to that in human beings. With dusts composed of mixtures of silica and other minerals the results are often disappointing even when the dust being tested is the apparent cause of human disease. Failure may be due to the time limitation imposed by the span of life of the ordinary laboratory animals or by the failure to appreciate and reproduce the complex factors of industrial exposure. Nevertheless the inhalation method may lead to an appreciation of these factors; it is establishing the conditions which govern the behavior of atmospheric suspensions of dust particles and those which determine inhalation into the lungs. It is elucidating the pathogenesis of various pneumoconioses in normal and in infected lungs.

By injection methods the experimenter may demonstrate the potentialities of any type of mineral to irritate

living tissues and may determine the character of the response. He must avoid technics which produce confusing nonspecific effects due to local trauma and the mere mechanical action of large amounts of any foreign body. This objection can be overcome by injecting dilute suspensions of particles at points remote from the site of ultimate localization. I prefer repeated intravenous injections of dilute suspensions of particles which permit gradual accumulation of the test substance in different organs. I have also employed the Miller-Sayers<sup>5</sup> intraperitoneal method; this gives good gross reactions but the microscopic pictures are hard to evaluate. Experiments with intratesticular injections are also in progress and may prove useful.

Since the objective is the determination of the capacity of a mineral to cause fibrosis, it generally makes very little difference whether its action is tested in the lung or in some other organ. Fibrous tissue develops from continued stimulation of connective tissue cells regardless of their location. As far as is known, these elements are just as capable of stimulation in the spleen or liver as in the lungs. In the case of free silica, this assumption has been proved beyond question, and furthermore it has been shown to hold good in any species of animal tested. The only apparent exceptions thus far discovered have been the fibrous minerals known as asbestos, which have produced little or no scar tissue outside the lungs. Reasons will be cited for suspecting that the fibrosis of asbestosis is due to mechanical irritation which is restricted to the lungs because of the active motion of this organ. In other locations the factor of rapid and continuous motion is lacking.

The etiology of the pneumoconioses will be discussed first from the point of view of the capacity of different minerals to irritate the tissues; the factors that govern the behavior of air-borne dust will then be considered, and finally the host factors that determine the amount of dust inhaled and modify the cellular reactions. For this consideration the minerals will be classified into groups consisting of free silica, combined silica, non-siliceous particles and mixtures composed of free silica and other substances.

A recent paper<sup>6</sup> reported uncompleted results of injections of physiologic solution of sodium chloride suspensions of different mineral particles into animals. These are summarized in tables taken from that publication but brought up to date when longer periods of observation have supervened. The capacity of different mineral particles of the same size and concentration to irritate the tissues is indicated by a series of numerals and plus signs. The significance of these symbols is indicated by the following definitions:

± Simple phagocytosis, often by giant cells, without other cellular reaction; no fibrosis.

+ Phagocytosis plus small localized collections of lymphocytes; reaction nonprogressive; no fibrosis.

2+ Similar to + but with more extensive infiltration of lymphoid cells; reaction nonprogressive; no fibrosis.

3+ Early proliferation of mononuclear cells, localized to immediate vicinity of primary phagocytes with further evidence of chronic inflammation. If any elements of fibrosis appear they are microscopic in extent and nonprogressive in character.

6. Gardner, L. U.: Reaction of the Living Body to Different Types of Mineral Dusts With and Without Complicating Infection. *Mining Technology*, May 1938.

4+ More extensive proliferation followed by fibrosis suggestive of early silicosis but not progressing to the mature hyaline stage.

5+ Typical, nodular, silicotic fibrosis, hyaline in character and progressive in type; the standard reaction.

6+ and 7+ Progressive fibrosis, hyaline in character but diffuse rather than nodular in form; observed only with two synthetic forms of free silica, cristobalite and tridymite.

8+ Acute toxic reactions with local necrosis of cells often resulting in death of the animal; little fibrosis in event of survival.

#### FREE SILICA

Table 1 sets forth the forms of free silica which have been tested by intravenous injection of 1 Gm. of particles of from 1 to 3 microns in diameter into the ear veins of rabbits and by other methods. The maximum period of observation in all cases has been eighteen or twenty-four months.

It will be noted that all the crystalline and crypto-crystalline forms of free silica are as active as or more active than the standard normal quartz. All of them have also produced progressive fibrosis of a silicotic type in guinea pigs, rabbits and white rats and in some cases other species. These results indicate that all the forms of free silica enumerated are capable of producing a progressive fibrosis if effective quantities remain in contact with living connective tissue. They

TABLE 1.—Free Silica

Vitreous silica.....	5+			Diatomite.....	5+

prove nothing as to the capacity of these forms of silica to remain suspended in the atmosphere and to be inhaled in dangerous quantities.

The observations on the amorphous varieties of free silica are more variable. Colloidal silica in a dispersed phase is exceedingly irritating and in too large an intravenous dose it causes almost immediate death. If the same suspension is allowed to gel either spontaneously or by changing its reaction, the silica promptly loses its irritating properties. The finely ground particles of the gel are phagocytosed by mononuclear cells, which subsequently develop epithelioid characteristics and often form giant cells of the Langhans type.<sup>7</sup> But with these transformations in the primary phagocyte, the manifestations of irritation cease; there is not even a local infiltration with lymphocytes to suggest any effect on the surrounding tissues. The picture has remained unchanged over a two year period; if anything the number of giant phagocytes has been less in animals killed two years after injection than in one killed at three months.

The natural minerals composed of amorphous silica, like opal and diatomaceous earth, are much more active. Pure diatomite produced a reaction which was indistinguishable from that to quartz, while opal caused a nonhyaline fibrosis which was atypical and which had begun to retrogress after a period of one year. In an attempt to explain this puzzling difference in the irritating properties of different forms of free amorphous silica, supplementary tests are being made with synthetic gels of variable water content. Eight months

after injection into the peritoneal cavities of guinea pigs not one of the six compounds has produced any appreciable fibrosis. The factor of water content can in all probability be eliminated. The desirability of testing other natural forms of amorphous silica is obvious.

Further supplementary tests have revealed pertinent facts with regard to the behavior of normal quartz and the other crystalline forms. The factor of dosage will be of more importance when the effects of mixed dusts are discussed. For pure, free, active silica the dose employed in all these tests has been excessive. As little as 0.05 Gm. of normal quartz will cause as much reaction as 1 Gm. in a 5 pound (2.3 Kg.) rabbit, but two years instead of one is required for mature reaction. A dose of 0.01 Gm. causes no visceral fibrosis, but the lymph nodes are still involved (the result of lymphatic drainage). Nevertheless the 1 Gm. dose has been used for the comparative study to insure the presence of adequate quantities of minerals that may be less irritating than quartz.

The rate and extent of tissue reaction are inversely proportional to particle size.<sup>8</sup> When the quartz is larger than 10 microns in diameter, reaction does not progress appreciably during a two year period of observation. Particles less than 1 micron in diameter cause increasingly acute inflammatory responses and often death from hepatic insufficiency within a few months. However, the size can be reduced to a point such that the particles are no longer retained in most parts of the body, and then their effect is again negligible. Intravenous injection of 1 Gm. of active vitreous silica particles with a maximum diameter of 0.002 micron produced no symptoms, but excessive amounts of silica were present in the urine. All the animals survived and when they were killed showed only minute foci of silicotic fibrosis.

Inhalation tests were also attempted with this fine dust to determine whether appreciable quantities would be retained in the lungs. The exposure to an undefined concentration of this very fine dust was continued for eight hours daily over a period of five months. At the end of this period pneumonia was making heavy inroads into the group, probably because of overcrowding in too small a dusting chamber. When the survivors were killed their lungs showed no fibrosis, but giant cells of the Langhans type were even more numerous than with larger quartz. It was concluded that some of the fine silica was retained, but in the absence of a method of measuring the atmospheric concentration the amount could not be estimated.

#### SILICATES

In a similar manner a group of representative silicates, most of which are used in industry, are being subjected to tests by animal injection. Table 2 summarizes the results as far as the observations have progressed. Not included in the table is a series of tests on synthetic sodium silicate. This substance is exceedingly toxic when the standard dose of 200 mg. is injected into the peritoneal cavity of guinea pigs. The animals die within a few minutes, exhibiting symptoms of silicic acid poisoning. Presumably its ready solubility is responsible for the toxicity of this silicate. Incidentally, repeated injections of minute quantities of the same substance into the lungs have

7. Gardner, L. U.: The Similarity of the Lesions Produced by Silica and by the Tubercle Bacillus, *Am. J. Path.* 13: 13-23 (Jan.) 1937.

8. Gardner, L. U., and Cummings, D. E.: Reaction to Fine and Medium Sized Quartz and Aluminum Oxide Particles: Silicotic Cirrhosis of the Liver, *Am. J. Path. (supp.)* 9: 751-763, 1933.

caused neither symptoms nor fibrosis, so that it seems fair to conclude that any quantity of sodium silicate which could be inhaled would be harmless.

As far as these observations have progressed, none of the silicates have proved capable of producing a fibrous type of reaction. Some of them, marked "(d)" in the table, have caused sudden deaths on intravenous injection into rabbits. Such reactions, owing either to mechanical occlusion of the blood vessels or to the toxic action of silicic acid formed in the preparation of the dust suspensions, probably have little to do with the subject under discussion. Beryl is apparently toxic and produces acute local inflammation that invariably leads to death. A few of the silicates, notably biotite mica and some of the clays, have provoked local proliferation of mononuclear phagocytes. Whether this early reaction will ultimately end in fibrosis awaits demonstration. If fibrosis should develop it will do so only after much longer contact with the tissues than is required in the case of free silica. Most of the silicates have excited an inert foreign body type of tissue response consisting of simple phagocytosis and giant cell formation with or without lymphocytic infiltration. Such reactions either have remained unchanged for periods of one or two years or have tended to retrogress. It is of interest to note that fibrous sericite of the type which Jones<sup>9</sup> stated might be such an important adjunct in the production of silicosis is among the most inert of the silicates.

Since the first publication on the action of silicates<sup>6</sup> the results of a few tests by still other methods have become available, which suggests that these tentative conclusions may need revision. When 5 mg. of suspensions of several different minerals was injected directly into the testes of guinea pigs it was found that the same feldspar produced a very active cellular proliferation within six months. Talc produced a less active response of a similar character. Garnet, sillimanite and platy sericite behaved in just the same manner as they did in the tests previously reported. The intratesticular injections involved excessive local concentrations, but the marked difference between the response to several silicates by this method and by the others employed suggests the necessity for further study. Possibly other silicates besides feldspar and talc will cause more reaction when sufficient quantities are thus concentrated in one small area. Time must demonstrate whether the initial change will progress to fibrosis. However, the practical significance of such massive doses remains doubtful.

#### ASBESTOS

The asbestos group of silicates, including anthophyllite, amosite, amphibole, crocidolite and chrysotile, have invariably failed to cause fibrosis or even early proliferation either intravenously in rabbits or in the peritoneal cavity of guinea pigs. Miller and Sayers<sup>5</sup> had a similar experience with three forms, chrysotile, amosite and crocidolite, and they classified them as inert substances. Obviously these observations are at variance with the well recognized capacity of asbestos to produce fibrosis of the lungs and demand explanation. One should not be too ready to condemn the method or to conclude that animals are incapable of reacting to asbestos. The method has worked consistently with free silica, and extensive pulmonary fibrosis has devel-

oped in guinea pigs when made to inhale chrysotile fibers. It is felt that the failure of these fibrous silicates to produce fibrosis in organs outside the lungs has real significance.

A very considerable number of observations are pointing to the hypothesis that the fibrous silicates behave in a different manner from the particulate minerals and that they irritate the lungs mechanically. Unlike quartz and the other active free silicas, not only have they failed to produce fibrosis in organs other than the lungs but they have not become more irritating as particle size decreases. Chrysotile fibers less than 3 microns in length are no more active than the silicate serpentine, which has the same chemical composition but is massive rather than fibrous in structure. Even by inhalation chrysotile, ground to such

fineness that its fibrous structure is no longer recognizable, has produced no suggestion of fibrosis after a year's exposure. If its action were chemical, the reduction in particle size should have resulted in an accelerated tissue response. The fibrosis of asbestosis that occurs in the lungs is not characterized by the hyaline transformation characteristic of the chemical action of free silica. In experimental animals, at least, the fibrosis of pulmonary asbestosis does not progress after exposure to the dust is discontinued, as invariably happens with free silica. All these observations suggest a mechanical rather than a chemical form of irritation. It has been inferred that reaction to asbestos is restricted to the lungs because only these organs possess the proper structure and physiologic activity to permit friction with a stiff fibrous foreign body.

The most obvious objection to this hypothesis is concerned with the formation of that peculiar structure known as the asbestosis body. It is produced by a thick coating of iron and probably organic material laid down on the surface of an asbestos fiber. The deposit

9. Jones, W. R.: Silicotic Lungs: The Minerals They Contain, J. Hyg. 33: 308-329 (Aug.) 1933.

is extremely irregular in outline with terminal globular swellings and numerous transverse haustrations. It is a golden yellow and, like the blood pigment hematin, it gives microchemical reactions to iron. In the lungs of guinea pigs, asbestos fibers must remain in contact with the tissues for about two months before the coating becomes recognizable. Asbestosis bodies also occur in man and have been reported in the lungs of brown rats.<sup>10</sup> In the lungs of cats, rabbits and white rats subjected to prolonged inhalation of asbestos dust they have never been discovered. In other organs they usually fail to develop; only in very rare instances have one or two bodies been detected in the peritoneal cavities of guinea pigs injected locally. They are reported as absent in the "asbestos corns" which appear on the hands of workmen handling this fibrous mineral.

The absence of asbestosis bodies in tissues other than the lungs suggests that chemical changes peculiar to that organ are responsible for their development. Since

tions of the first three to six months will be followed by fibrosis. Other silicates of a fibrous structure may act as mechanical irritants in organs with appropriate architecture and functional activity.

#### SILICON CARBIDE

One compound of silicon, which is not a silicate but a carbide, deserves special mention because it has such widespread industrial use as an abrasive. It is known to commerce by various trade names such as "carborundum" and "crystolon." By any of the injection methods it has failed to cause even a suggestion of fibrosis. The particles are phagocytosed by cells which merely enlarge to accommodate the foreign bodies in their cytoplasm without the "epithelioid" alterations suggestive of slight toxicity. There has been no change in the original picture within a period of two years after the injection of the standard doses. In the scheme employed throughout this work the reaction to silicon carbide has been classified as  $\pm$ . After inhalation for a period of two and one-half years the lungs show excessive focal accumulations of dust associated with slight degrees of chronic inflammation. The lack of fibrosis following the injection of particles of this exceedingly hard abrasive constitutes very good evidence for rejecting the properties of hardness and sharpness as a cause of such reaction.

#### NONSILICEOUS MINERALS

Similar tests have been performed with a number of pure minerals containing no silica. As indicated in table 3, none of them have caused primary fibrosis; a few have provoked slight chronic inflammatory reactions; some have been toxic. With large doses selected as standard, the "toxic" minerals have either caused immediate death (e.g., dolomite) or excited acute inflammations the healing of which resulted in scar formation. The response to massive doses of toxic substances, such as the sulfides, has no bearing on the subject of pneumoconiosis, in which the quantities inhaled could never approximate those used for injections.

Aside from the toxic reactions that healed with the formation of more or less scar tissue, none of these nonsiliceous dusts have produced any fibrosis. Diamond, the hardest known mineral, and aluminum oxide, a common abrasive in industry, are inert. Soft coal is slightly more irritating than anthracite. The reaction to the satin spar form of gypsum will in all probability prove to be quite inert when the tests are completed. It so happened that the last animal of the series to be killed showed somewhat more chronic inflammation than other members of the series, so that its effect is noted as "2 + ?" in the table.

#### MIXTURES OF FREE SILICA WITH OTHER MINERALS

Apparently there are certain substances capable of depressing the action of silica, and there may be others which accelerate it. As long ago as 1918 Haldane<sup>12</sup> expressed the belief that coal dust inhaled at the same time as silica prevented the development of silicosis. His belief was based on clinical statistics and on experiments performed by Mavrogordato.<sup>13</sup> By 1929 the latter seems to have lost faith in these observations, for he wrote "The presence of carbon in the air does not

a fibrous reaction has been observed only in the tissues where the bodies have been numerous,<sup>11</sup> the question arises as to whether the chemical changes responsible for the deposit on the mineral fiber is the same one that affects the tissues of the host. No answer is yet available, but it is quite conceivable that the two effects are independent of each other. It has been suggested that the irritated tissues attempt to protect themselves by laying down the coating, and as a matter of observation subcutaneous injection of asbestosis bodies recovered by digesting human lung tissue with antiformalin has caused no fibrosis in guinea pigs.

These observations would suggest that as a class the silicate minerals are not irritating because they contain silica, which is liberated by chemical action of body fluids. A few of them, like biotite mica, beryl and some of the kaolins, seem to have essential molecular structures capable of provoking acute inflammation or early proliferation. Their action has not been followed long enough to demonstrate whether these early reac-

appear to affect the changes produced by silica other than coloring them." Apparently most clinical observers also gave up the Haldane theory of a protective action by coal dust after several years.

Recently, however, experimental pathologists have renewed their interest in the idea. I have long been impressed by two observations; it is not at all difficult to produce nodular fibrosis by making small laboratory animals inhale relatively pure, free silica, but they do not react in a similar manner to mixed dusts in which the silica is associated with considerable amounts of other minerals. Prolonged inhalations of heavy concentrations of natural mixtures such as granite and ferruginous chert or of artificial mixtures composed of fine quartz and gypsum dust have not produced an effect commensurate with the quantity of silica available in the atmosphere. Rather than condemn the inadequacy of the experimental method, I have attempted to discover whether there are reasons for the apparent failures.

Injectations indicate that the presence of various other minerals in a mixture may retard the usual reaction to silica, restricting the extent of tissue involvement and modifying the form of the cellular response. Different classes of minerals seem to be capable of acting in this manner. Some of them occur in natural combination with free silica; others have been added artificially. Not enough is known about inhibitors to evaluate their effects quantitatively or to attempt to classify them, but their action is sufficiently striking to deserve more than passing mention.

Table 4 summarizes the experience in a long series of experiments based on injection and on inhalation of mixtures of some form of active silica and other minerals. The table indicates that injection produces much more reaction than exposure by inhalation to a dust of the same composition. Even on injection, however, the response to a given quantity of silica is modified. Both the rate at which reaction develops and its intensity are affected. Quite naturally the modification is most marked in cases in which nonsiliceous elements are found in excess.

Table 4 indicates that a variety of minerals may inhibit the action of quartz in the body: iron oxide, coal and some constituent of granite, probably the silicates (feldspar or mica), but perhaps some other element present in smaller amounts. The series would suggest that inhibition is most effective in the presence of small amounts of silica. The experience with anthracite coal and crude fluorite which are contaminated with practically the same quantities of silica implies that not all inhibitors are equally potent. The reactions to the different doses of granite and chert are indicative of the relative importance of the two factors dosage and time. In the various tests on these two minerals, from three to ten times the quantity of silica necessary to produce marked progressive fibrosis has been injected, but in the presence of inhibitors cellular reaction has been delayed. In the case of granite, mature fibrosis has never appeared, and even after twenty-two months the cellular picture is the same as that produced by the quartz alone in one or two months. In chert the proportion of silica to iron oxide is higher, and hence it should not be concluded that iron is a less effective inhibitor.

The consistent results observed in all animals used to test this series of minerals containing increasing proportions of free silica makes it seem most probable that the principle of inhibition is a valid one. The mecha-

nism by which inhibitors exert their effects has yet to be demonstrated. The bearing on the general problem of etiology is obvious, for one must conclude that the rate and severity of reaction do not depend solely on the amount of free silica in the mixture. They are inversely affected by the other components of the dust.

The dust from the South African gold mine contained 70 per cent of quartz and yet even in this proportion the silica is somewhat inhibited. Reaction developed slowly, and after sixteen months the silicotic lesions were less advanced than those of the pure quartz standard. Incidentally the sericite, which with platy muscovite and a trace of feldspar and possibly ilemite make up the remaining 30 per cent of this mixture, has failed to accelerate the action of the quartz as Jones hypothesized. Experimentally it has not itself caused fibrosis nor has it accentuated the effect of free silica.

There still remains for consideration the evidence which has been interpreted as indicative of accelerator

† In one or two animals nodular fibrosis (4+) developed in the lymph nodes draining the lungs but pulmonary fibrosis was lacking.

substances. The matter came to light in the examination of a few persons engaged in the manufacture of soap powders who died after exposures of a few months or years. The first cases were reported by MacDonald, Piggot and Gilder<sup>14</sup> in England, and subsequently a few more were found by Chapman<sup>15</sup> and others in this country. It was shown that the soap powder contained large amounts of very fine silica and appreciable quantities of free alkali. On the basis of the solubility hypothesis it was postulated that unusual quantities of silica had dissolved in the alkaline medium and that a more rapid reaction had consequently developed. However, when some of these persons died and came to autopsy their lungs showed complicating tuberculosis.<sup>16</sup> A few sections from one of Chapman's patients reviewed by me revealed no evidence of complicating infection, but unfortunately such small blocks of tissue were available that one could not be certain that isolated foci of infection had been overlooked.

McCord, Fleming, Ainslee and Johnston<sup>17</sup> injected silica with alkalis into the peritoneal cavity of guinea pigs and found that the "primary toxicity" of silica was increased (one out of four of their animals injected with 0.4 Gm. of a mixture of equal parts of either quartz or silica gel and sodium bicarbonate died in four days). There was a wider dispersion of lesions than in the quartz control animals but there was "no proof of either accelerator or inhibitor action of alkalis in the production of silicotic nodules."

The similarity between the lesions found in the various "soap powder cases" and those in sand blasters and in certain tunnel workers<sup>18</sup> suggests the possibility that the rapidity and character of the cellular response might have been produced equally well by excessive concentrations of exceedingly fine particles. Definite proof of acceleration by alkalis is still lacking. It would be more logical to expect an immediate, acute, toxic reaction, the result which McCord and his associates obtained by injection.

**Solubility of Silica.**—Because so much has been written on the solubility of silica as the cause of its irritating properties, mention must be made of the attempts to evaluate this factor. It will be recalled that "the solubility hypothesis" was based on experimental proof of the toxicity of colloidal silica and the fact that quartz is slightly soluble in dilute alkalis. It was postulated that, since the reaction of the mammalian body is slightly alkaline, very fine particles of inhaled quartz might slowly dissolve and form the toxic colloid in the lungs.

Actual demonstration of solution of particulate silica in the living body is difficult both because the amounts are extremely small and because many tissues already contain small but variable quantities of silica which are apparently derived from ingested food. Gravimetric methods of analysis are inadequate to detect minute increases in quantity, and they do not differentiate between undissolved particles and silica in solution. In 1933 King and Stantial<sup>19</sup> modified Isaac's colorimetric method for determining soluble silica for use on biologic material so that it is now possible to detect minute quantities. To ascertain whether such silica is in true molecular solution or in the form of a colloidal suspension, the clear fluid is passed through an ultrafilter to remove the colloidal aggregates. According to King and McGeorge<sup>20</sup> the filtrate theoretically contains only silica in molecular solution.

By this method King, Stantial and Dolan<sup>19</sup> demonstrated an excess of silica in the urine of animals injected with soluble forms of this substance but lesser amounts when relatively insoluble quartz was substituted. They also reported that the urine of silicotic miners contained from four to five times as much silica as that of normal subjects. The latter observation was apparently confirmed by Sayers and Goldman<sup>21</sup> on a group of anthracite coal miners. Goldwater<sup>22</sup> then

showed that the excretion of silica in normal human beings changes from day to day and that even on similar diets the urinary output varies in different workmen. Dworski<sup>23</sup> has confirmed Goldwater's observations and discovered that in addition to the leafy vegetables, which are generally recognized as the major source of ingested silica, certain brands of beer contain surprising amounts of this mineral. Drinking even a half a bottle of such beer will more than double the usual output of silica in the urine. On following the daily excretion in a group of nine tuberculous silicotic miners on ordinary diets for a period of months he found that in six of them the average output in twenty-four hours exceeded the daily average for a control group of normal subjects. However, only two had an average excretion greater than the maximum twenty-four hour output of the controls. In general it would appear that the daily fluctuation in urinary silica of normal persons is greater than the excess in the silicotic over the normal group. At the present time it is not generally conceded that the excretion of silica in the urine is of particular etiology or diagnostic significance.

Theoretically it is debatable whether enough inhaled quartz can be dissolved, produce local tissue reactions and leave a surplus to be excreted in the urine. Comparatively small numbers of particles are inhaled into the pulmonary air spaces at any one time. They are phagocytosed and transported into localized areas where nodular fibrosis then develops. As evidence of local toxic action on the cells there are degenerative changes in the phagocytes and peculiar alterations in collagen. The former closely simulate the "epithelioid" degeneration produced by the tubercle bacillus; the latter consist of swelling, hyalinization and increased absorption of acid dyes. Although it has never been proved, it would seem very likely that most of the soluble silica would be fixed and retained in such reactions. Kraut<sup>24</sup> and later King and his associates<sup>25</sup> demonstrated little or no excess of silica in the blood of persons with silicosis. If it is carried in the blood to the kidneys for excretion it must exist in some other form than the toxic colloid, for anatomic evidence of damage to the kidneys or other organs is lacking. The statistical conclusions of Collis and Yule<sup>26</sup> that all the organs of the body are more frequently diseased in silicotic than in other subjects lack confirmation. To me it still seems probable that if the silica is dissolved most of it combines with the tissues in the immediate vicinity of the particles and that the soluble silica demonstrated in the urine is very largely derived from different foods. A carefully controlled study of the silica balance in hospitalized silicotic and normal subjects is indicated.

Recently many reports have appeared which deal with the solubility of silica outside the body. Some of them can be criticized on technical grounds. For example, Emmons and Wilcox<sup>27</sup> reported the solubilities of fine particles of quartz, flint and various silicates in blood serums. The particles were agitated in the serum at body temperature for periods of several

weeks; portions of the suspension were then centrifuged at ordinary speeds (up to 3,500 revolutions per minute) to remove the particles, and the supernatant fluids were then analyzed gravimetrically for silica. Since it is doubtful whether all the particles less than 3 microns in diameter were removed from the viscid blood serum by centrifugation and since they determined silica by gravimetric analysis, which would detect both solid and dissolved material, their figures are probably too high.

Titus<sup>28</sup> attempted to overcome these difficulties by separating the particulate silica with an ultrafilter and by analyzing the filtrate colorimetrically, a method which should reveal only dissolved material. But King and McGeorge<sup>29</sup> point out that the dissolved material may exist in both colloidal and molecular solutions. As the colloidal ultrafilters remove not only particulate silica but also colloidal aggregates of dissolved silica, it is their opinion that Titus's very low solubility figures are also erroneous.

In the Saranac Laboratory the amount of soluble silica has been determined colorimetrically on all the physiologic salt solution suspensions of mineral particles used for testing animals. The particles in all cases are of a standard size; all are less than 3 microns in maximum diameter but in many instances those smaller than 1 micron have not been previously removed by elutriation. The suspensions are allowed to stand in a refrigerator until the supernatant fluid is water clear; a portion is decanted and centrifuged at high speed. Although one cannot be positive that every particle has been eliminated by this process, none can be seen; but even if particles were present they would not influence the result of the colorimetric analysis. The figures for free silica in these suspensions vary from values like 5.2 parts per million for active normal quartz to 205 for less active opal. In the case of the silicates the range is equally wide; the slightly irritating clay halloysite yielded 4.5 parts per million, while inert fibrous anthophyllite gave a figure of 124.2. The significance of these results remains to be demonstrated; the obvious deduction is that there is no parallel between the capacity of a siliceous mineral to produce reaction and its degree of solubility in physiologic solution of sodium chloride. Within wide limits the least soluble forms tend to be the most active tissue irritants, but even this is not always the case. For example, normal quartz and diatomite exhibit essentially the same capacity to form fibrosis and yet their corresponding solubility figures are 5.2 and 35 respectively. The moderately irritating opal yielded 205 parts per million of soluble silica, while inert silica gel gave 125 parts of soluble silica. Denny, Robson and Irwin<sup>29</sup> have shown that the solubilities of different samples of pure quartz vary widely, but no one has ever demonstrated a corresponding variation in the rate of capacity to provoke fibrosis. If these test tube experiments parallel conditions in the body, it would seem that some other factor besides solution in water is essential to the production of silicosis.

The last named authors and, shortly thereafter, Briscoe, Matthews, Holt and Sanderson<sup>30</sup> discovered that the addition of other minerals materially affected the

solubility of quartz in water. For example, Denny and his associates reported that the addition of 1 per cent of fine metallic aluminum reduced the solubility of one sample of quartz from 50 to 1.9 parts per million. It was rendered more soluble by adding small quantities of the carbonates and hydroxides of magnesium, sodium, potassium and calcium. Briscoe and his co-workers likewise observed modified solubility of quartz but not always in the same manner and to the same degree; they reported that added magnesium carbonate, alumina and zinc oxide had no apparent effect on the yield of soluble silica from calcined flint, asbestos or feldspar.

These observations *in vitro* are most difficult to evaluate at the present time. The marked influence of other substances on solubility of silica suggests that such experiments may not be directly applicable to the living body. Attempts have been made to overcome the objection by substituting serum or ascitic fluid for water or salt solution as a solvent. King and McGeorge<sup>29</sup> report solubility figures for free and combined silica in these fluids which were comparable to those reported for water. Dworski<sup>23</sup> has obtained similar results in a few tests on normal quartz. King and McGeorge found, however, that the rate of solution was greater with several forms of free silica than with a few of the silicates. But even the use of a body fluid may not approximate conditions in the lungs, where change in hydrogen ion concentration may be more frequent and where the presence of appreciable quantities of other inhaled mineral particles may influence solubility.

Regardless of the mechanisms involved, all the experimental evidence tends to confirm the belief that fibrosis is to be expected only from various forms of free silica and from those silicates which have a fibrous structure; i. e., asbestos. The free silica need not necessarily be of crystalline form; one of the amorphous varieties has proved as active as normal quartz, although others were practically inert. A few of the silicates are toxic; others have produced mild degrees of cellular proliferation. If any of them ultimately cause fibrosis, such reaction must be extremely slow in development. Particles of certain other minerals naturally or artificially associated with free silica delay the development of silicotic fibrosis and modify its form. Whether all nonsiliceous minerals may act as inhibitors awaits demonstration. Definite proof of accelerators to the action of silica is yet lacking; it has been suggested that cases of "rapid silicosis" in human beings may be due to excessive exposures to silica or unusual fineness with or without associated infection.

Some information has been gained on the nature of the irritation produced by different minerals. It may be stated with reasonable certainty that the mechanical factors of hardness and sharpness play no part in the irritation from particulate minerals. With the fibrous silicates mechanical irritation is strongly suspected, although final proof is still lacking. The validity of the solubility hypothesis to explain the unusual activity of free silica has been questioned, and attention has been called to certain apparently well substantiated observations which are not consistent with the hypothesis as now conceived.

#### DUST INHALATION

*Atmospheric Factors.*—As already intimated, there are factors which exert a very marked influence on the behavior of dust suspended in air. If the dust is of

28. Titus, A. B.: Silica and Silicate Solubilities, *J. Indust. Hyg.* 19:138-145 (March) 1937.

uniform composition the factors of specific gravity, particle size, capacity to absorb water and agglutinability largely determine how long it will remain in suspension. Obviously very heavy or very large particles will settle more quickly than smaller and lighter ones; those which remain separated longer than those which clump together and form heavy aggregates. The factor of particle size is of primary importance and has been the one most extensively studied. Sayers<sup>31</sup> has published a graph in which settling velocities are plotted against diameter for particles of various specific gravities. Most particles smaller than 1 micron in diameter settle at a rate of from 1 to 3 feet per hour. When the diameter exceeds 5 microns specific gravity has more influence; for a specific gravity of 7 the rate is 60 feet per hour, for 2.6, the specific gravity of quartz, it is only 25 feet per hour. With the exception of the fibrous materials, it may be said that any particle greater than 10 microns in diameter settles so rapidly that it plays a minor role in the formation of dust.

If the dust is produced from material of complex structure it should not be assumed, as is so often done,

TABLE 5.—Experiments on Inhalation

Type of Rock	Particle Size	Silica Content			Dust from Lungs, 1 to 2 Years' Exposure
		Ground Dust	Rafter Sample	Air-Floted Dust	
Ferruginous chert A	50% > 3 microns Aver. 15 microns 50% < 3 microns Aver. 2 microns	51%	35%	10.5%	3.30%
Ferruginous chert B	93% < 2 microns	67.55	60.0	41.0	16.30
Mixture A Gypsum 1 part Quartz 1 part	All < 3 microns	49.70	53.7	23.3	.....
Mixture B Gypsum 2 parts Quartz 1 part	All < 3 microns	31.40	36.1	17.7	11.20
Quartz control	All < 3 microns	91.24	....	....	43.39

that the proportions of each constituent mineral will be the same either in the air or in the dust settled on the rafters as it was in the original rock. Variations in hardness and brittleness of different components will determine the size to which each will fracture. With a given expenditure of force a hard, tough mineral such as quartz will be broken into larger particles than softer materials. Because of their greater size the quartz particles may largely settle out of suspension, leaving an atmospheric dust composed chiefly of nonsiliceous matter. Numerous experimental and field studies made by the Saranac Laboratory have revealed convincing evidence of such variation in composition. A few examples are cited in the proceedings of the Third Symposium on Silicosis, held in 1937.<sup>31a</sup> Others are to be published in the near future. Hatch and Moke<sup>32</sup> found for example that in foundries the rafter dust might reveal 50 per cent or more of silica but that in air-floated material only 2.3 per cent of the particles under 10 microns in diameter were quartz. Subsequently Moke<sup>32a</sup> retracted his original conclusions because of

errors attributed to his methods of analysis. Even then he was unable to ascertain the exact proportion of free silica in the atmosphere owing to the nature of the other components in the dust. In view of my own experience I am inclined to believe that the original conclusions of Hatch and Moke are still valid. Although many codes are still based on the silica content of the rock to be worked and numerous reports refer to analyses made on samples taken from rafters, it can be appreciated that such figures are not likely to be a reliable index of a dust hazard.

While differences in size, shape and specific gravity may influence the relative settling rates of individual particles in a mixed dust, the factor of agglutination also comes into play and probably has more significance than is the case of dusts composed of only one element. Particles of different physical or chemical structure often agglutinate to form masses so large that they cannot remain in suspension. Opposite electrostatic charges or hygroscopic properties are among the possible causes. If one of the elements happens to be free silica, agglutination with particles of some other mineral may materially reduce the percentage of silica remaining in the atmosphere. Examples of this effect will be cited later when the last group of factors has been discussed.

*Factors of Protective Action of the Upper Respiratory Tract.*—Whether the upper respiratory tract exerts any selective action on different kinds of mineral particles is unknown, but it would seem probable that dusts which are easily wet would be retained more readily than others. From an examination of the mineral particles which have gained access to the lung it is obvious that the protective mechanisms exclude practically all particulate material greater than 10 microns in diameter but that fibrous foreign bodies are not so effectively handled. Fibers of asbestos as long as 150 to 200 microns have been found in the alveoli. It would seem reasonable that aggregates of particles should be excluded in much the same manner as large single particles.

Probably because of the protective action of the upper respiratory tract, the composition of the mineral particles recovered from the lungs is often very different from that of the original rock and sometimes from the dust resulting from its manipulation. Examples from experiments on inhalation are illustrated in table 5.

The total concentrations of atmospheric dust as measured by the impinger method at the breathing level inside the animals' cages were excessive, for the four different experiments cited the average counts of particles less than 10 microns in diameter visible by light field illumination were as follows: chert A, 98,200,000; chert B, 551,800,000; gypsum-quartz mixture A, 319,000,000; gypsum-quartz mixture B, 303,000,000. By dark field illumination these figures were at least four times as high. In each of the chert experiments daily exposures of eight hours continued over a period of two years have failed to produce silicosis in rabbits, guinea pigs and white rats; only nonfibrous patches of chronic pneumonitis resulted. After three years, immature nodular foci of proliferation began to make their appearance.

During similar exposures to both of the artificial mixtures of quartz and gypsum, a few animals which were killed between the twentieth and the twenty-second month have revealed a limited number of atypical hya-

line silicotic nodules in their lungs; those which survived longer had had no nodules but only the non-specific pneumonitis.<sup>33</sup>

The explanation for the retarded development or the absence of silicotic reaction to the inhalation of these mixtures probably involves both the extrinsic and the intrinsic factors that have been discussed. In the case of the ferruginous chert, table 5 indicates that little silica had accumulated in the lung after exposure of one year. What did accumulate would be subject to the modifying action of the iron, previously demonstrated by injection. After three years of exposure enough silica had accumulated to cause reaction, but in the presence of the inhibitor the lesions were still immature and atypical. In the case of the gypsum-quartz mixtures the atmospheric factors were the only ones that have been evaluated. The table indicates low silica values for the lung ash in comparison with the quartz control series. After two and one-half years of exposure appreciable quantities of silica had begun to accumulate, but only in certain animals. Perhaps these were animals in which the protective action of the upper respiratory tract was deficient. The possible effect of intrinsic inhibitory factors has not been tested by injection of gypsum with quartz. In the case of granite dust the results of injection strongly suggest that the inhibition occurs inside the body, but here the extrinsic factors were not tested because facilities for chemical analysis were not available when the inhalation experiments were being made.

Similar inhibitory effects have been reported for metallic aluminum by Denny, Robson and Irwin.<sup>29</sup> These investigators found that the addition of only 1 part of aluminum to 100 parts of freshly fractured quartz prevented the development of silicosis in rabbits. In controls similarly exposed to pure quartz for sixteen hours a day perfectly typical early silicosis developed in six months. Their chemical analyses demonstrated as much silica in the lungs of the experimental animals as in the controls. In this case the inhibition unquestionably occurred inside the body.

Evidences of inhibitory action are not confined to experiments on animals; in industrial plants, reductions in the proportion of inhalable atmospheric silica have been repeatedly demonstrated and delayed responses to silica in mixed dusts are not uncommon. The studies of Hatch and Moke<sup>32</sup> on the reduction of the silica content in the atmosphere of foundries has already been mentioned. Similar observations have been made in unpublished surveys of cement and gypsum plants by Durkan.<sup>34</sup> In the former a quickly setting cement is made by adding a certain quantity of finely ground silica. In an intensive survey of conditions in seventeen such plants a theoretical dust hazard was anticipated from this process, but counts and analyses of the atmospheric dust showed low concentrations of silica at the breathing level. Physical and roentgenographic examinations of the workmen, more than 1,300 in number, have revealed only one person with silicosis attributable to mixtures of silica and cement dust. This man had had a severe crushing injury involving his face and nose which may well have been responsible. A damaged nose could easily impair the effectiveness of the upper respiratory protective

mechanisms. In the gypsum industry, so-called "sanded plaster" was formerly made by mixing considerable quantities of fine and coarse sand with calcined gypsum. Here again the theoretical hazard was found not to exist after a study of the atmosphere and of the employees exposed. By special arrangement with their employers seventeen men, many of them retired, who had had long exposures in making this particular product were located and examined. Both physical and roentgenographic examinations failed to disclose a single case which was even suggestive of silicosis.

But on the other hand it may be objected that silicosis does develop in human beings who are exposed to mixtures of silica and other substances. As a matter of fact there are relatively few industrial atmospheres which are not mixtures, and silicosis does develop in many workmen when the silica content of the dust is sufficiently high. If so many fine silica particles are projected into the air that the other minerals fail to remove them they will be inhaled, but in many cases evidence of inhibitory action will still be manifested by a slow development of pulmonary disease. As examples, the very industries whose dusts have been the subject of experimental study may be cited: granite cutting and hematite mining. If one compares the average exposures that were necessary to produce demonstrable silicosis before the introduction of modern protective methods it will be found that they are much longer in these industries than in ones handling relatively pure silica. In the granite industry exposures of from fifteen to twenty years are commonly necessary to provoke nodular fibrosis; in the hematite mines the average is in excess of twenty years. With the purer silica dust of the lead and zinc mines of Picher, Okla., and the South African gold mines silicosis used to develop in from three to seven years.

In the past it has been customary to explain these variations in the rate of response in different industries on a basis of the relative quantities of free silica in the atmosphere. But the high total concentrations that are known to have existed before the campaign for the prevention of dust began to be effective have made this simple explanation seem inadequate. The action of the two sets of factors just described, one acting outside the body to reduce the amount of silica inhaled and the other inside the lungs to delay and modify the irritating effects of silica, may offer a more satisfactory explanation. Their effects are just beginning to be appreciated, and it will obviously require more study to determine their relative importance in any industrial atmosphere. At the present time it hardly seems justifiable to add protector substances to a siliceous dust as a prophylactic measure; at least, until more is known about the subject, the aim should be to decrease rather than increase the total amount of dust in the atmosphere.

#### FACTORS OF INDIVIDUAL SUSCEPTIBILITY

Up to this point the development of silicosis has been considered from the point of view of the group, and only average periods of exposure have been considered. It is a matter of common knowledge that not all members of any group react to inhaled dust in the same manner nor at the same rate. Every observer has been impressed with the fact that under the former conditions of employment only about one fourth of any group of miners of hard rock would develop silicosis while the other 75 per cent, apparently exposed in the

33. For reasons to be determined, the second gypsum-quartz mixture (2:1) was more active than the first, although the calculated quantities of silica at the breathing zone were almost the same in the two experiments.

34. Durkan, T. M.: Unpublished data from Saranac Laboratory.

same manner, seemed to be immune. Many explanations have been proposed but none are satisfactory. Some have believed that those who escaped were merely persons who did not happen to be exposed to enough dust for a sufficient period of time; some have held that the victims were mouth breathers or persons with deficient upper respiratory protective mechanisms, and still others have entertained the possibility of innate variations in the capacity of tissues to react to silica and other minerals. All investigators are agreed that coexistent pulmonary infection and particularly tuberculous infection plays a profound part in modifying individual susceptibility to inhaled dust.

It is obviously most difficult to prove whether any person in a large plant or even in a particular part of that plant has been subjected to the same quantity and quality of dust as his fellows. What has already been said of the variations discovered in a small experimental chamber 8 by 8 by 8 feet indicates the possibilities in the large spaces of a mine or foundry. Dust counts and analyses may give some idea of average conditions if they are repeated sufficiently often, but no occupational history could possibly account for the rapid local fluctuation and summation of their effects.

Much has been written on effective nasal filtration in preventing or retarding the development of pneumoconiosis. Lehmann<sup>35</sup> has measured the efficiency of the nasal passages in miners and discovered that among men without silicosis 63 per cent had retention efficiencies for inhaled silica dust of over 40, and only 18 per cent fell below 30. In miners with silicosis only 20 per cent of the group had nasal efficiencies over 40, while 62 per cent were classified as less than 30. Lehmann like other observers feels that mouth breathers are in particular danger. These observations seem logical but they have not been confirmed, owing to the difficulty of making the measurements.

There is as yet no proof that the tissues of different normal persons vary in their capacity to react to irritating minerals. With the large doses of free silica employed for the injection tests every animal in any series has exhibited a similar response, and a capacity to react to silica has been proved for various mammals, birds, amphibians and fish. Possibly the injection of much smaller doses would demonstrate individual differences. A most desirable contribution would be a large series of chemical analyses of the lungs of both silicotic and nonsilicotic members of a human group exposed to some siliceous dust for a significant period of years. Intensive biochemical studies of both groups are also needed to answer this question.

The factor of infection is the cause for variation in susceptibility which has been studied most intensively. Relatively little is known of the effect of infections in the upper respiratory tract, although it is assumed that such conditions modify the protective mechanisms.

In the case of the lungs themselves there is no doubt of the etiologic significance of chronic infections. This complication may produce anatomic alterations which mechanically influence the deposition of inhaled dust, and it may possibly act in more subtle ways to alter the tissue responses to certain kinds of dust.

The mechanical effects are familiar and most easily understood. In normal lungs inhaled particles are probably distributed quite uniformly throughout the

organs, except for a tendency to accumulation in the subpleural air spaces. By the agency of mobile phagocytes, ordinary quantities of such particles are removed from the air spaces and transported to the lymphatic vessels. Through the latter the foreign bodies are carried to lymphoid tissues situated both within and at the roots of the lungs. The development of a focus of chronic infection interferes with this orderly process of deposition and elimination. Appreciable numbers of air spaces may be obliterated by granulation or scar tissue, and the lymphatic drainage from the affected area is disturbed or perhaps destroyed. Particles of dust accumulate in increasing numbers about and within such an area of disease. The pigmented scars of healed tuberculosis in the apexes of the lungs are familiar examples of this tendency. The infectious process may be more extensive and may possibly have exhibited a considerable degree of pathologic activity during periods of inhalation of dust, but the same tendency to local accumulation is manifested. The subsequent development of emphysema and other changes to be discussed in the section on pathology may then make it appear that all the dust has localized in the region of the infection.

The more subtle influences of infection and particularly tuberculous infection in apparently altering the capacity of the lungs to react to siliceous dusts are not well understood. There are some investigators who believe that mature silicotic lesions never develop except in the presence of an element of infection. I do not subscribe to this view as I believe that the injection and inhalation experiments with pure silica have reproduced nodular fibrosis under conditions in which infection can be excluded. Nevertheless I admit that in some human lungs with even a localized focus of healed tuberculosis the nodules of silicotic fibrosis throughout all parts of the organs are of unusual size and appearance. I<sup>36</sup> have repeatedly maintained that the tubercle bacillus and silica dust in combination can produce results which neither irritant alone will do. With mixtures of free silica and other substances the inhibitors have not had their usual effects in animals infected with tubercle bacilli. The silicotic lesions have progressed more rapidly, and, while the tuberculous element has either healed or become very chronic, much more fibrosis has developed than with either infection or the dust alone. I have entertained the hypothesis that at least some of the silicates may prove to be more active on a background of infection than in normal lungs. Uncompleted experimental observations lend some support to this view, but the only silicate with which conclusive results have thus far been attained is chrysotile asbestos. Inhalation of this dust in association with any pulmonary infection has caused healing with much more fibrosis than either infection or asbestos alone. All these points will be more fully discussed in the section on pathology. Here it suffices to state that chronic infectious lesions and particularly those due to tuberculosis alter the localization and accumulation of all dusts in the lungs, that under proper circumstances they accentuate the development of silicotic fibrosis and that they permit both mixtures of free silica with other dusts and the silicate asbestos to produce unusual amounts of scar tissue.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION  
OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

### NU-HESIVE SURGICAL DRESSINGS ACCEPTABLE

Manufacturer: Diadem Surgicals, Inc., Leominster, Mass.

New products utilizing Nu-Hesive Gauze Bandage as a base (acceptance published in *THE JOURNAL*, March 30, 1935, p. 1073) are recommended for use as sterile bandage or dressing material. Nu-Hesive is a nonabsorbent, porous material that traps excretions, adheres only to itself, and does not shrink when wet. Gauze is impregnated with a practically nonabsorbent cohesive latex which leaves the interstices of the fabric partially open. In addition to the Nu-Hesive Gauze Bandage previously accepted, the line includes Bias Bandage, Dia-Dressings, Finger Wraps, Gauze Tape Bandage and Ortho-Hesive Athletic Tape.

**Nu-Hesive Bias Bandage:** A bias bandage having considerable elasticity and binding pressure, in a range of sizes, used where excessive swelling is imminent or a slight flexing of the joint is desired.

**Nu-Hesive Dia-Dressings:** A prepared sterile compress, recommended in wet applications and as a dressing for boils, and ulcers. It is wrapped in individual glassine envelopes.

**Nu-Hesive Finger Wraps:** A prepared, sterile finger dressing, for minor injuries, wrapped in glassine envelopes.

**Nu-Hesive Gauze Tape Bandage:** A combination, nonshrinking tape and gauze bandage, packed in sterile rolls, especially useful in wet dressings.

**Nu-Hesive Ortho-Hesive Athletic Tape:** Primarily designed for ankle strapping for athletes; also useful in ankle and wrist support in serious sprain cases. Normal muscle flexing is permitted by a primary give or spring, and support becomes effective immediately following the limit of normal muscle action. The Ortho-Hesive Athletic Tape is not subjected to the same sterilization process since it is not intended to be used in contact with open wounds.

The firm was asked to substantiate the claims made for sterility and in reply submitted laboratory records, photographs of the testing laboratory in the finishing and packing rooms, and a test rack containing samples which had each been incubated for at least ninety-six hours at 37 C.

In addition, the materials were subjected to a bacteriologic examination by a competent medical man, at the Council's instigation. The report is abstracted here:

**Materials and Methods.**—Culture medium consisted of nutrient broth in large tubes (50 cc. in each tube) which was sterilized by 15 pounds steam pressure for twenty-five minutes. Instruments used in handling the gauze were wrapped in paper and sterilized by exposure to a temperature of 160-170 C. for at least two hours. All manipulations were carried out in a glass-walled box with an opening in the bottom on one side for the operator's arm. This opening was swabbed out thoroughly with saponated solution of cresol and kept closed for several hours before use.

The rolls of gauze were carefully unwrapped at one end and then securely grasped with a pair of heavy forceps by inserting one jaw through the hole in the center of the roll and the other jaw through the inner turns of the gauze. The wrapper was then entirely removed without allowing the outside of the wrapper to touch the gauze. By means of a safety razor blade held in a hemostat a number of deep cuts 0.5 cm. apart were made across the roll of gauze parallel to its axis. By means of a pair of forceps these sections were lifted out and placed immediately in the culture tubes. The inner spool, together with the few remaining turns of the gauze, was also cultured so that the entire roll of gauze was cultured each time.

The Finger Wraps and Dia-Dressings were opened by cutting off the end of the containing envelop. With sterile forceps the gauze was removed, rolled into a small roll and the entire piece placed in a culture tube. The tubes were incubated at 37 C.; half of the tubes of each series were incubated aerobically, the other half anaerobically in a sealed jar. It was shown that *Clostridium sporogenes* grew readily in broth tubes in the jar.

With each series of gauze culturing a number of broth tubes were opened and closed in the same manner as those receiving the gauze. These were incubated both aerobically and anaerobically.

**Summary of Results.**—One hundred and sixteen pieces of gauze, representing all the products submitted, were cultured in nutrient broth aerobically and anaerobically. No bacteria grew in any of the tubes. On inoculation of these tubes with *Staphylococcus aureus* and *Bacillus subtilis* growth occurred readily, with the exception of four series.

These were numbers 2, 9, 19 and 20, consisting of one-half inch Gauze Tape Bandage, 1½ inch Gauze Tape Bandage, 3 inch Bias Bandage and 4 Dia-Dressings (2 inches by 4 inches) respectively. Only slight growth in these showed that there is one inhibitory substance that is present in some of the preparations of gauze. This inhibition could not be correlated with any type of gauze or time of incubation. Since the inhibition was present in only a few of the rolls and then not in sufficient degree to prevent bacterial growth entirely, no attempt was made to remove the inhibitory substance. The tubes not showing this inhibition on inoculation showed as much growth as the control tubes.

It may be said that no bacteria were cultured from the products submitted, under conditions in which growth of ordinary bacteria occurred readily.

In view of the foregoing report, the Council on Physical Therapy voted to reaccept the Nu-Hesive Gauze Bandage and accept the Bias Bandage, Dia-Dressings, Finger Wraps, Gauze Tape Bandage and Ortho-Hesive Athletic Tape.

### EMERSON HUMIDOX HUMIDIFIER ACCEPTABLE

Manufacturer: J. H. Emerson, 22 Cottage Park Avenue, Cambridge, Mass.

The Emerson Humidox is a humidifier for use in connection with an oxygen regulator and nasal catheter for administering oxygen to patients. It consists of a quart preserve jar with a metal cover equipped with an inlet which is attached to the regulator and an outlet which leads to the catheter. The inlet pipe goes to the bottom of the jar, which is partially filled with water. At the lower end of this pipe is a porous filter which breaks up the oxygen into very fine bubbles, allowing it to take up slightly more moisture than would be possible with an ordinary wash bottle, according to the firm.

The apparatus may be purchased with a carrying case and additional equipment including a regulator, catheter and wrench. When the Aircor float type gage is used, corrections have to be made for the indicated flow. These are mentioned in the direction sheets.

With the large cover of the preserve jar held in place by a resilient fastener, any excess pressure causes this to act as a safety valve. Water does not pass through the walls of the porous filter rapidly, which aids in preventing sudden high pressures from escaping from the regulator into the jar and hence to the patient. In addition, it acts as a protection in case the humidifying jar is tipped over.

A separate heater may be hung on the humidifier. This raises the temperature of the water from 10 to 15 degrees, depending on the size of heating element used (from 10 to 30 watts). It is claimed that the warmed oxygen is better for the patient.

The only therapeutic claim made for the device by the manufacturer is that it will reduce the danger of drying out the nasal passages and the oropharyngeal mucosa when oxygen is being administered by nasal catheter.

In order to substantiate claims made for the unit, it was investigated clinically by a competent physician. He reported that it rendered satisfactory service.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Emerson Humidox Humidifier for inclusion in its list of accepted devices.

Emerson Humidox.

SATURDAY, NOVEMBER 19, 1938

## ANIMAL EXPERIMENTATION AND SCIENTIFIC MEDICINE ENDORSED BY VOTERS

The voters of California and Colorado, November 8, by overwhelming majorities emphatically rejected proposals made in those states to undermine the structure of scientific medicine. In California an initiative humane pound law, so called, proposing to cripple scientific research by hampering animal experimentation, was decisively defeated. In Colorado an initiative measure proposed by a group of chiropractors, to debase the quality of medical care in the state by repealing the basic science act and by destroying other safeguards that have been erected to assure adequate and scientific medical service, was met by an avalanche of negative votes, running as high as ten to one in some counties.

In Oklahoma an initiative measure that would have sanctioned practices not conducive to public welfare failed to get on the ballot, because of court action instituted by the medical profession. In Ohio a chiropractic initiative somewhat similar to the Colorado initiative died aborning, the cultist sponsors apparently becoming disheartened shortly after the proposal was submitted to the attorney general for his approval as to form. Petitions in Ohio were not circulated and the proposed initiative measure was not submitted to the people for a vote.

The medical associations in the states named assumed the lead in thwarting the selfish interests behind these proposals, interests that would subordinate the public welfare to their own private ends. In California and Colorado the state medical associations, aided by many lay and other professional groups and by public spirited citizens, informed the people fully of the dangers implicit in the proposals. To bring these dangers to the attention of the voters necessitated great sacrifices of time and money, but the results show that such sacrifices were well worth while and indicate that an informed electorate will support scientific medical care under proper legal and ethical safeguards.

## INJURIES TO THE RECURRENT LARYNGEAL NERVE

The recurrent laryngeal nerve is a branch of the vagus nerve which on the right side arises in front of the subclavian artery and on the left side to the left of the arch of the aorta. On each side the nerve ascends in the groove between the trachea and the esophagus and enters the larynx, branches going to all the muscles except the cricothyroideus. An injury to both recurrent nerves in the course of a thyroid operation is a calamity.

The prevailing attitude of surgeons toward the recurrent nerves, which is partly erroneous, has been unchanged from the beginning of thyroid surgery. Kocher's position in advocating that partial thyroidectomy be done under local anesthesia so that, in having the patient speak, the surgeon might learn that the recurrent nerves were not injured, was unsound. There are temporary changes in the voice in some patients immediately after and probably during thyroid operations without injury to the recurrent nerves, and, if the voice change does indicate an injury to the nerve, the damage has already been done. Other unsubstantiated impressions about the recurrent nerves have been accepted for many years. Surgeons have assumed that the nerves were too small to dissect and that, when possible, dissection would result in recurrent nerve paralysis. It has also been assumed that direct suture of severed recurrent nerves was impossible because the nerves could not be found in the scar tissue following subtotal thyroidectomy and if found they would be too small to suture. Recent experience at the Lahey Clinic<sup>1</sup> has shown that these assumptions are false. Three years ago Lahey undertook to demonstrate the recurrent nerve in practically all thyroid operations. To date the surgeons of that clinic have dissected more than 3,000 recurrent nerves, thus showing not only that the nerve is sufficiently large to be dissected but that it can be palpated as it is pushed laterally against the tracheal wall; also that routine dissection and even palpation while on a moderate stretch cause no interference with function. Moreover, this experience has proved that the routine exposure of recurrent nerves in thyroid surgery will diminish, if not largely eliminate, injuries to that nerve.

There is still some confusion about the clinical features of recurrent laryngeal nerve paralyses. If the recurrent nerves are interrupted there is usually little difficulty with the patient's breathing during the operation, but immediately after the operation the patient is unable to talk because of loss of innervation of the vocal cords. Frequently within six months the patient may report that the voice is returning. Somewhat later the patient will complain of inability to breathe satisfactorily after any unusual activity, and this condition will progress until there is difficulty with breathing on

1. Lahey, Frank H., and Hoover, Walter B.: Injuries to the Recurrent Laryngeal Nerve in Thyroid Operations; Their Management and Avoidance, *Ann. Surg.* 108: 545 (Oct.) 1938.

slight exertion. Permanent bilateral abductor paralysis causes obstruction of the larynx by the mesial position of the vocal cords, relief from which often necessitates the permanent use of a tracheotomy tube.

After demonstrating the ease with which severed recurrent nerves can be approximated, Lahey states that, in all cases in which there is such an injury which does not disappear in three months, the nerve should be explored and the ends refreshed and anastomosed. The previous attitude generally has been that in such injuries nothing much could be done. In a case in which both nerves had been severed elsewhere ten months previously they were found and anastomosed without difficulty. One great difficulty of suturing recurrent nerves is that of approximating abductor fibers with abductor fibers and adductor fibers with adductor fibers. At present it is impossible to say whether restoration of double impulse nerve conduction in a single trunk can ever be successfully accomplished. One should, however, in anastomosing recurrent nerves make every effort to unite them so that there may be at least a reasonable chance of fibers conveying similar impulses being opposed to each other. With magnifying lenses it can be seen that the nerve is somewhat flattened. In uniting it the surgeon should place the two ends of the nerve in the same flat plane and with no twist in them. When more than half an inch to an inch is lost it is doubtful whether the severed ends of the nerve will come together.

Even though thyroid surgery is now well established on a sound basis, there is still need for more interest among surgeons in diminishing the incidence of injury to recurrent laryngeal nerves.

#### MIXED TUMORS OF THE LUNG

Discrepancies between the microscopic diagnosis and the clinical behavior of tumors are not infrequent. Cole<sup>1</sup> has recently cited many examples of gastric ulcer in which the estimation of malignancy varied decisively among various diagnosticians. A newer and more difficult problem concerns the diagnosis of tumors of the bronchi.

Formerly tumors of the lung were considered rare and quite unsusceptible of surgical attack, even when benign. Now, however, the point of view has changed. Not only are benign tumors considered suitable for successful surgical excision but even malignant neoplasms have been shown to be removable with comparative safety and with a reasonable chance of cure. With the emphasis on early diagnosis has come the identification of the early clinical manifestation of these tumors. The symptoms produced by pulmonary tumors are now becoming more generally known. With the advent of bronchoscopy their early stages are actually seen and biopsy specimens obtained and studied. Whereas our

knowledge of neoplasms of the lung was formerly based on necropsy material, now bronchoscopic examinations with study of biopsy specimens are more frequent. With this advance has come an apparent increase in the incidence of such lesions but with it a confusion as to their actual nature. Especially important is the estimation of the malignancy of these early tumors. On such a diagnosis must rest the decision as to the most appropriate type of therapy. Many of them have been called adenomas, others have been described as polyps, a few as chondromas, fibromas, angiomas and neurofibromas.

When a patient complains of chronic cough, hemoptysis, pain in the chest or unexplained fever, the diagnosis of influenza or unresolved pneumonia may seem logical and correct. In many instances, however, a small tumor will be found occluding a bronchus, producing atelectasis or associated with pulmonary suppuration. With bronchoscopic relief of the obstruction the symptoms may disappear. However, microscopic study of the excised tissue may reveal a benign or a malignant lesion. Shall it be treated with diathermy, roentgen therapy or radium, or does surgical excision offer the only secure hope of cure? The answer to these questions is the subject of an anatomic and clinical study of many of these cases, recently reported in the *Ludvig Hektoen festschrift* by Womack and Graham.<sup>2</sup> These observers present evidence to show that many pulmonary neoplasms resemble fetal pulmonary tissue and arise from the failure of embryonic buds to develop into normal structures. Recognizing their similarity of behavior and in some respects their similarity of origin to the mixed tumors of the parotid gland, these workers have described this group of neoplasms as mixed tumors of the lung and have built up a histologic and clinical entity to fit their observations.

This new concept of pulmonary neoplasms will probably go far to explain the discrepancies which have been experienced in the microscopic appearance and clinical behavior of many tumors of the lung. As Womack and Graham point out, these tumors arise from entoderm and mesoderm and hence may take various forms depending on the tissue they resemble. More important is the fact that these tumors, though at first benign, may eventually develop into carcinoma and are to be considered, therefore, as potentially malignant. By the time they do become malignant their pathogenesis is lost and they may look like the ordinary type of bronchiogenic carcinoma. Thus is explained the failure of postmortem studies to recognize this group of tumors. With the realization of their common origin as mixed tumors, Womack and Graham feel on the basis of their studies that such terms as adenocarcinoma, alveolar carcinoma, mucous gland carcinoma, "oat cell" carcinoma and round cell carcinoma are now untenable. With this simplification in the terminology as well as

1. Cole, L. G.: *The Pathological Yardstick: Its Accuracy as an Instrument for Measuring Errors in Clinical, Roentgenological and Surgical Diagnosis of Gastric Lesions*, Surg., Gynec. & Obst. **63**: 689 (Dec.) 1936.

2. Womack, N. A., and Graham, E. A.: *Mixed Tumors of the Lung: So-called Bronchial or Pulmonary Adenoma*, Arch. Path. **26**: 165 (July) 1938.

pathogenesis, the study of the early manifestations of pulmonary neoplasms will be facilitated. Perhaps the growing incidence of the late stage of inoperable cancer of the lung may be halted by a recognition of the lesion which in many cases seems to be its precursor.

## Current Comment

### BUILD OF WOMEN AND MORTALITY

In a preliminary report read before the Association of Life Insurance Medical Directors of America, Dublin and Marks<sup>1</sup> discussed the results of their investigations on the relation of height and weight of women to the death rate. Their descriptive tables are based on 329,627 policies and their mortality tables on 308,228 policies—material extensive enough for statistical conclusions in most classes even though derived from the experience of a single company. When all heights were combined, the most favorable mortality in ages under 30 was found among those slightly (from 5 to 14 per cent) and moderately (from 15 to 24 per cent) overweight; but the ratios for these groups were not significantly different from those of average weight. From these low levels the mortality increased to its highest point in the 25 to 35 per cent overweight, followed closely by those from 15 to 24 per cent underweight. At ages 30 to 39 the situation was in many respects similar. At ages 40 to 49 the best mortality was recorded among those slightly below average weight, and at ages 50 and over the most advantageous mortality was among those who were underweight. In the aggregate the mortality of women of short height has been distinctly above the average, and the ratio of actual to expected deaths was 109 per cent for this group as compared with 98.8 per cent recorded for both medium height and tall women. This excess mortality of short height women appeared in every age group. At ages under 30 the most favorable mortality was recorded among medium height women, but between 30 and 39 tall women have done best. In women over 40 there was in the aggregate no marked difference between the mortality ratio and the medium height and tall women. When related to specific diseases, mortality from tuberculosis was 60 per cent higher among those 15 per cent or more underweight than the average for the group. In those 15 per cent or more overweight the mortality was only 33 per cent of the expected. The mortality from pneumonia and influenza followed a similar pattern. Deaths from lobar pneumonia were highest among the underweight and those considerably overweight, although this trend showed much variation with age. For the chronic cardiovascular and renal conditions there was a fairly steady progression of the ratios from the lowest levels in the underweight groups to the highest in the overweight groups. Acute heart and kidney disease, on the other hand, tended toward high frequency among the underweight. Diabetes showed the typical correlation between weight and mortality far more distinctly than did most

other causes. The most striking differences in mortality were found in diseases of the gallbladder and biliary passages, where there was an unmistakable progression of mortality from a low point among the underweight to a high point among those who were more extremely overweight. This study, while of a preliminary nature, apparently serves to confirm the general assumption that has been made in the insurance business with regard to the build of women; namely, that they present a situation similar to that disclosed by the studies of the influence of build on mortality among men. Furthermore, these authors believe, the anthropometric data indicate the need of some revision of the standard height-weight table, which is too smooth and therefore probably disregards fundamental changes in weight according to age during adult life. It is their opinion that median weights are probably better than mean weights because the latter are unduly influenced by extreme overweight.

### TRANSPLANTATION OF HUMAN CANCER INTO RABBITS

Recently successful transplantation of human cancer into the anterior chamber of the rabbit eye has been reported. This is potentially an exceedingly important contribution to experimental pathologic technic. About a year ago Greene and Saxon<sup>2</sup> of the Rockefeller Institute, Princeton, N. J., tested the autoplasmic and homoplastic transplantability of rabbit uterine adenomas and adenocarcinomas. While autotransplantations were invariably successful, intratesticular, subcutaneous, intramuscular and intraperitoneal transplantations into a new host invariably failed. Transplantations into the anterior chamber of the eye of a new host, however, were successful in a large percentage of the cases. After growth for from three to five serial transplants in the anterior chamber of the eye, successful transplants could be made into the testicle. With this encouraging result, the Rockefeller Institute experimenters retested the possibility of heteroplastic transplantation. Heteroplastic transfer of mammalian tissues is generally considered impossible. Two tumors, an adenocarcinoma of the rabbit uterus and an adenocarcinoma of the rabbit breast, however, were successfully transplanted into the guinea pig eye. Serial transplants through three generations were effected, a process which apparently could be continued indefinitely. In his latest report Greene<sup>2</sup> tells of attempts at similar heteroplastic transplantation of a human breast tumor. Seven successful takes were obtained in twelve attempted transplantations into the anterior chamber of the rabbit eye. Growth first became apparent toward the end of the third week, with vascularization readily visible during the sixth week. Following vascularization the growth rate increased. Since the behavior of the human cancer grafts in the rabbit eye conforms in all respects to those of rabbit tumors in the guinea pig eye, Greene believes that human tissues can thus be maintained and cultivated indefinitely in the rabbit. If so, his technic may be applicable to a wide range of physiologic and pathologic problems not associated with malignant growths.

# ORGANIZATION SECTION

## HOUSE OF DELEGATES COMMITTEE MEETS WITH INTERDEPARTMENTAL COMMITTEE

On October 30 the Committee of the House of Delegates of the American Medical Association, including Dr. Irvin Abell, President of the Association, as chairman; Dr. Walter F. Donaldson, Pittsburgh; Dr. Walter E. Vest, Huntington, W. Va.; Dr. Henry A. Luce, Detroit; Dr. Fred W. Rankin, Lexington, Ky.; Dr. Frederic E. Sondern, New York; Dr. E. H. Cary of Dallas, Texas, with Dr. Rock Sleyster, President-Elect of the American Medical Association, and Dr. Olin West, Secretary, ex officio, met with the Interdepartmental Committee to Coordinate Health and Welfare Activities of the Government in Washington. The Interdepartmental Committee arranged for attendance by several members of its own Technical Committee, and the American Medical Association group was accompanied by Dr. W. C. Woodward of the Bureau of Legal Medicine and Medical Legislation and Dr. R. G. Leland and Mr. Jack D. Laux of the Bureau of Medical Economics.

In a joint interview, following the conference, by Dr. Irvin Abell and Miss Josephine Roche, it was pointed out that the conference had reached no definite conclusions or specific plans for cooperation, nor had there been any abandonment of specific positions taken by either group in relationship to the program. The representatives of the government again explained the detailed concept of the National Health Program. The representatives of the American Medical Association indicated the actions taken by the House of Delegates, which involved approval of the extension of public health service specifically related to the prevention of disease and the provision of hospitals and allied

institutions and of government assistance for the care of the indigent when the need can be established. The medical representatives pointed out that in hospitalization and the care of the indigent the administration should be simple and placed in the hands of responsible public officials who would cooperate with local medical societies. The medical representatives again expressed opposition to compulsory sickness insurance and the fear of the fact that the insistence on such a system by the government would be "bureaucratic, costly and political."

In a brief report on the conference, President Irvin Abell said:

The reception accorded our committee was quite friendly and the discussions evinced the same spirit on both sides. They were fruitful in bringing out a better understanding of opposing points of view and in focusing attention on the discrepancies in data and statistics on which such points of view are founded. While tentative agreement in principle, not in methods of application, was reached on four of the recommendations, the conference was stymied by the question of compulsory sickness insurance. The Interdepartmental Committee is to hold conferences with representatives of other groups, notably the American Public Health Association, the American Dental Association, the American Hospital Association and the American Nursing Association. It was suggested that our committee return at a later date for further conference presumably after the above named organizations, through their representatives, have had opportunity to express their views. If this invitation is accepted an early date was suggested, as the Interdepartmental Committee will prepare its report to be submitted to the President at the opening of the Congress, when its recommendations may be embodied in proposed legislation.

## ABSTRACT OF REPORT OF SPECIAL COMMITTEE OF THE AMERICAN DENTAL ASSOCIATION

Your committee [of the House of Delegates of the American Dental Association] has drawn up the following declaration of principles and recommendations which it believes should be presented by the American Dental Association to the federal government for its assistance in planning the dental phase of a general health program.

Your committee recommends that in the formulation of any national health program the American Dental Association should insist on including the following principles:

I. In all conferences that may lead to the formation of a plan relative to a national health program, there must be participation by authorized representatives of the American Dental Association.

II. The plan should give careful consideration to: first, the needs of the people; second, the obligation to the taxpayers; third, the service to be rendered; and, fourth, the interests of the profession.

III. The plan should be flexible so as to be adaptable to local conditions.

IV. There must be complete exclusion of nonprofessional, profit-seeking agencies.

V. The dental phase of a national health program should be approached on a basis of prevention of dental diseases.

VI. The plan should provide for an extensive program of dental health education for the control of dental diseases.

VII. The plan should include provision for rendering the highest quality of dental service to those of the population whose economic status, in the opinion of their local authorities, will not permit them to provide such service for themselves, to the extent of antepartum care, the detection and correction of dental defects in children, and such other service as is necessary to health and the rehabilitation of both children and adults.

VIII. For the protection of the public, the plan shall provide that the dental profession shall assume responsibility for determining the quality and method of any service to be rendered.

### RECOMMENDATIONS

Your committee has considered the five recommendations of the Technical Committee and, so far as they apply to dental service, makes recommendations as follows:

*Expansion of Public Health and Maternal and Child Health Services.*—Expansion of General Public Health Services: 1. We approve of the general expansion of public health services and, in addition, recommend the establishment of a federal Department of Health with a secretary who shall be a graduate in medicine, and a member of the President's cabinet; and a first assistant secretary who shall be a graduate in dentistry.

2. In an expanded public health program which involves a consideration of the expenditure of millions of dollars for public health purposes, your committee recommends that the problem of dental caries and other dental diseases be included.

*Medical Care for the Medically Needy and a General Program of Medical Care.*—1. Your committee is convinced that satisfactory dental service cannot be rendered under a compulsory health insurance system. We therefore do not favor such a plan but do approve voluntary budget plans under professional control which will enable patients to "apportion costs and timing of payments so as to reduce the burdens of [dental] costs and remove the economic barriers which now militate against the receipt of adequate [dental] care."<sup>1</sup> [The word "dental" was substituted by the committee for the word "medical" in the original quotation.]

2. The committee approves the recommendation that such a program should provide for "continuing and increased incentives to the development and maintenance of high standards of professional preparation and professional service."<sup>1</sup>

#### CONCLUSION

Your committee agrees with the Technical Committee's belief "that, as progress is made toward the control of various diseases and conditions, as facilities and services commensurate with the high standards of American medical practice are made more generally

available, the coming decade, under a national health program, will see a major reduction in needless loss of life and suffering—an increasing prospect of longer years of productive, self-supporting life in our population."<sup>2</sup> We also believe that the above statements apply equally to dental practice and that the enumerated benefits would be enhanced by early and regular dental care in childhood.

Your committee offers two final recommendations:

1. In view of the fact that dental caries is the most prevalent disease of mankind, the American Dental Association strongly recommends that the federal government augment, with a comprehensive research program, the efforts of the organized dental profession to determine the cause of this disease.

2. That in keeping with the first main principle of this report, a committee of five practicing dentists be appointed by the Board of Trustees, together with such technical advisers as the needs of the committee require, to fulfil the provisions of principle I.

#### COMMITTEE

HOMER ROBISON.	W. O. TALBOT.
CRAFT A. HOPPER.	ALFRED WALKER.
E. E. VOYLES.	STANLEY RICE.
HENRY CLINE FIXOTT.	R. J. RINEHART.
HAROLD W. OPPICE, Chairman.	

1. "A National Health Program," recommendation 4, paragraph 4.

2. "A National Health Program," recommendation 5, last paragraph.

## OFFICIAL NOTES

### HEARINGS BEFORE THE GRAND JURY IN WASHINGTON

In addition to witnesses mentioned in recent issues of THE JOURNAL, the newspapers report the following persons as having appeared last week before the Special Grand Jury in Washington, D. C.: Dr. Lewis H. Taylor, president of the Sibley Hospital; Mr. and Mrs. Charles Hardin; Mr. Sherwood Booth; Miss Tommie Lee Nix and Miss Elizabeth Tew, employees of the Home Owners' Loan Corporation; Miss Taylor Owen (the last three were said to be members of the Group Hospital Association, Inc.); Mrs. Peggy O'Connor and Mr. James R. Adams, both employees of the WPA; Miss Sarah Abbott, Mrs. Harriet A. Austin, Mr. and Mrs. H. P. Avery, all said to be members of the Group Health Association, Inc., and Dr. William W. Bauer, director, Bureau of Health Education, American Medical Association. The Grand Jury is also said to have had before it during the last week records of Garfield Memorial Hospital, brought by Dr. Francis J. Eisenman, superintendent, and records of Columbia Hospital for Women and Lying-In Asylum, brought by Col. P. M. Ashburn, superintendent of that hospital.

### RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the

National Broadcasting Company, entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-six weeks. The program is broadcast over the Blue network of the National Broadcasting Company each Wednesday at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).<sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next six programs to be broadcast, together with their dates and their topics, are as follows:

November 23.	Weather and Wearing Apparel.
November 30.	Rest, Relaxation and Recreation.
December 7.	Tuberculosis and the Teens.
December 14.	What Shall We Eat?
December 21.	Hidden Treasures in Foods.
December 28.	Good Milk, Good for You.

1. Owing to program conflicts, there will be no Chicago broadcast of the network program. Instead, a recording of the program will be broadcast over Station WENR at 8 p. m. each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

## WOMAN'S AUXILIARY

### California

The Santa Barbara County auxiliary recently gave \$34 to the troupe of Girl Scouts it sponsors in order that two girls might attend camp two weeks each.—At a benefit dinner at the residence of Dr. and Mrs. William Daniel, Pasadena, \$370.66 was realized with which a resuscitator for babies was purchased and presented to St. Luke's Hospital, Pasadena.—The Santa Clara County auxiliary is holding a series of 50 cent teas in private homes, the profit from which is turned over to the

charitable fund, with which a number of children each year are sent to camps.

### Washington

Mrs. J. B. Robertson of the auxiliary to Pierce County Medical Society, Tacoma, won the special cash prize of \$25 offered by the "Hygeia" Committee of the Woman's Auxiliary to the American Medical Association for the best paper on "The Value of 'Hygeia' to the Medical Profession." Only the auxiliaries winning cash prizes or honorable mention in the second Hygeia annual contest were eligible to participate.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### CALIFORNIA

**Proposed "Humane Pound" Law Defeated.**—The so-called humane pound initiative measure was defeated in the California election November 8 by a margin of more than two to one, according to press reports. Up to November 10 the totals were 1,259,014 votes against the measure and 593,934 in its favor.

**Changes in Health Officers.**—Dr. Alexander B. Bigler has been appointed city health officer of Chowchilla, succeeding Dr. Alton C. Atwood. Dr. Cornwall C. Everman is health officer of Larkspur and Dr. David G. Smith of Corte Madera; both of these communities were formerly served by Dr. Louis L. Robinson. The city of Needles has transferred the administration of its public health affairs to the San Bernardino County full time health unit; Dr. Walter W. Fenton is the health officer of the county. Dr. Frederick W. Knight has been appointed health officer of Corcoran to succeed the late Dr. James H. Van Vorhis.

### CONNECTICUT

**Society News.**—Dr. Morton Arnold, Willimantic, addressed the Tolland County Medical Association October 18 in Somers on "Treatment of Common Diseases of the Ear, Nose and Throat."—The Hartford County Medical Society was addressed October 25 in Bristol by Dr. Abraham Myerson, Boston, on "Relationship of the Autonomic Nervous System to Pharmacology."—Dr. John A. Hartwell, New York, discussed "Trends in Medical Practice" before the New Haven County Medical Association October 27.—Dr. Rudolf Schoenheimer, New York, discussed "Studies in Protein Metabolism with the Aid of Heavy Nitrogen" before the Yale Medical Society November 9 in New Haven.

**Changes in Health Officers.**—Dr. Robert E. Perdue was appointed the first full time health officer of Norwalk, effective September 1. Norwalk is now the ninth city in Connecticut to be on a full time basis. Dr. William Sherman Randall has been appointed health officer of Shelton to fill the unexpired term of the late Dr. John E. Black. Dr. Donald J. McCrann, West Hartford, has succeeded Dr. Maurice B. Thompson as health officer of Bloomfield. Dr. Archibald M. Gaulocher, Wingdale, N. Y., is health officer of Kent and Dr. Frank D. Ursone, Norfolk, health officer of Colebrook. Dr. Edward J. Brophy is health officer of Norwich, filling the unexpired term of the late Dr. Harrison Gray.

### DELAWARE

**State Medical Election.**—Dr. Meredith I. Samuel, Wilmington, was elected president of the Medical Society of Delaware at its annual meeting in Dover October 12. Other newly elected officers are Drs. Bruce Barnes, Seaford, and Charles G. Harmonson, Smyrna, vice presidents; John H. Mullin, Wilmington, secretary, and Alfred L. Heck, Wilmington, treasurer.

### ILLINOIS

**New District Health Units.**—A new district health department has been established in Woodstock to serve the counties of Boone, Lake, McHenry and Winnebago. Dr. John F. Shronts is the district health officer.—Dr. Maurice Gore, Aurora, has been appointed medical officer in charge of the new health district embracing the counties of DeKalb, Grundy, Kane, Kendall and LaSalle. A new unit including Bond, Clinton, Madison and St. Clair counties has been placed under the direction of Dr. Claude Milton Eberhart, Highland.

### Chicago

**Personal.**—Dr. Paul C. Barton, since 1934 a member of the staff of the Council on Pharmacy and Chemistry, has been appointed Director of the Bureau of Investigation of the American Medical Association. Following graduation from the University of Maryland School of Medicine, Baltimore, and completion of his internship, Dr. Barton spent several years in private practice.—Mrs. Lucille Smith, director of

medical service for the Chicago Relief Administration, resigned October 6 to accept a position with the Social Security Board in Washington, D. C., newspapers reported.

**Symposium on Blood Transfusions.**—The Chicago Medical Society devoted its meeting November 9 to a symposium on blood transfusions. The following spoke:

Dr. Bernard Fantus, The Blood Bank of Cook County Hospital (Preserved Blood versus Fresh Blood).  
Dr. Elizabeth H. Schirmer, Blood Preservation Technic.  
Dr. Karl A. Meyer, Blood Transfusion Technic.  
Dr. Lindon Seed, Blood Transfusion Reaction.  
Dr. Egbert H. Fell, Transfusion of Fresh Blood.  
Dr. Josiah J. Moore, Practical Possibilities of Private Blood Banks.

### IOWA

**Symposium on Fractures.**—A symposium on fractures was presented before the Pottawattamie County Medical Society in Council Bluffs November 7 by the following:

Dr. Robert D. Schrock, Omaha, Fractures of the Ulna and Radius at the Wrist.  
Dr. Hiram Winnett Orr, Lincoln, Neb., Prevention and Control of Infection in Fractures and Other Bone Surgery.  
Dr. Arthur Steindler, Iowa City, Fracture Deformities of the Ankle.  
Dr. Karl R. Wernsdorff, Council Bluffs, Fractures of the Spine.  
Dr. Charles L. Scudder, Boston, Regional Fracture Committees of the United States and Fractures of the Os Calcis.

**Refresher Courses.**—Two refresher courses in obstetrics and pediatrics opened early in October in the eleventh and ninth councilor districts, under the auspices of the speakers' bureau of the state medical society, the State University of Iowa College of Medicine, Iowa City, the Iowa Pediatric Club, the Central Association of Obstetricians and Gynecologists and the state department of health. In the eleventh district the first two meetings were held in Atlantic, the next three in Red Oak, and the last three will be given in Harlan. The entire program for the ninth district is being presented in Chariton. The speakers include Drs. Everett D. Plass, John H. Randall, William F. Mengert, Philip C. Jeans, Julian D. Boyd, all of Iowa City; Robert M. Collins and Jack V. Treynor, Council Bluffs; Robert H. McBride, Sioux City, and Fred Moore, Des Moines.

### LOUISIANA

**Society News.**—At a meeting of the Orleans Parish Medical Society in New Orleans October 24 the speakers were Drs. Lucien A. LeDoux on influence and effects of toxemias on menstruation; Leon J. Menville, "Treatment of Advanced Carcinoma of the Cervix," and Robert H. Bayley and David E. Fader, "Congenital Cystic Lung Disease."—Dr. Harold R. Cummings, Los Angeles, gave a talk on Metchnikoff before the Tulane History of Medicine Society, New Orleans, October 21.

**Drive Against Illegal Practitioners.**—J. E. Garret was fined \$100 for practicing medicine without a license and \$1,000 for selling improperly labeled products in court at Abbeville recently; \$700 of the larger fine was suspended. Newspapers reported this as the first major conviction obtained by the state board of health in its drive against the illegal practice of medicine and the misbranding of preparations. It was also stated that forty manufacturers who had not registered with the board applied for certification of their products after recent seizure of eighteen uncertified products.

### MARYLAND

**Dr. Williams Reappointed Commissioner of Health.**—Dr. Huntington Williams has been reappointed commissioner of health of Baltimore for another term of six years. Dr. Williams first became commissioner Jan. 31, 1933, after having served as director of health from Oct. 1, 1931.

**Parrots Forbidden in Baltimore.**—The mayor and city council of Baltimore approved an ordinance October 3 prohibiting bringing into, offering for sale, selling, giving away or breeding within the limits of Baltimore parrots, parakeets, love birds, macaws, cockatoos, lorics, lorikeets and other birds of the psittacine family. The ordinance provides that zoologic gardens operated under public authority or laboratories in which scientific research is being carried out may receive or import birds of the psittacine family in conformity with such rules and regulations as prescribed by the city department of health.

**Society News.**—The Baltimore City Medical Society met with the Medical Society of the District of Columbia November 16 in Washington; the speakers were Drs. Edmund L. Keeney on "Slow Epinephrine"; Hugh H. Young, "Genital Abnormalities of Hermaphroditism and Related Adrenal Diseases," and Monte Edwards, "Rectal Lymphogranuloma."

Dr. William Barry Wood Jr. addressed the Baltimore society November 4 on "Treatment of Lobar Pneumonia." A symposium on vitamins was presented before the Baltimore society October 21 by Drs. Julius Friedenwald on "Gastrointestinal Aspects"; Paul W. Clough, "Neurologic Aspects," and Esther L. Richards, "Psychiatric Aspects."

### MICHIGAN

**Society News.**—Dr. James A. Conner, Chicago, addressed the medical section of the Wayne County Medical Society, Detroit, October 10, on "Treatment of Pertussis." The surgical section was addressed October 24 by Dr. Hans Finsterer, Vienna, Austria, on "Surgical Treatment of Acute Gallbladder Diseases and the Common Duct Obstructions."—Dr. Sabina Kessler-Frux, Bay City, was elected president of the Michigan branch of the American Medical Women's Association at the annual meeting in Detroit in September, succeeding Dr. Mary Margaret Frazer, Detroit.

**Course in Basic Ophthalmology.**—A new course in basic ophthalmology began November 1 at Wayne University College of Medicine, Detroit, to continue each Tuesday and Friday throughout the year. Designed for residents and those interested in increasing their basic knowledge in ophthalmology, the first course is on histology, comparative and human, while the second will be in physiologic optics, physiology of the eye, gross anatomic sections of the head and neck and so on. There is no fee for the courses. Dr. Parker Heath is professor and head of the department of ophthalmology.

**Changes in Health Officers.**—Dr. Philip E. M. Bourland, Lansing, recently associated with the state board of health, has been appointed director of the Dickinson County health unit, succeeding Dr. Clifton E. Merritt, Bay City, who accepted a similar position in Bay County. Dr. Russell E. Pleune, Lansing, who was scheduled to take over the post in Dickinson County, is now director of the health unit, succeeding Dr. Forrest J. . . . Dr. Guy R. Post, Fremont, has resigned as director of the Tri-County Health Unit, serving Newaygo, Lake and Oceana counties, effective September 15. Dr. Reuben J. Harrington, for fourteen years health officer of Muskegon, has been appointed in charge of the unit in Muskegon County, succeeding Dr. Richard Sears of the state department of health. Dr. Clifton C. Corkill, Ontonagon, director of the Ontonagon-Baraga counties health unit, has been appointed in charge of the Menominee County health department. He succeeds Dr. Lawrence A. Berg, Detroit, who is on a year's leave of absence to take a graduate course at the University of Michigan Medical School.

### MINNESOTA

**Research in Food Technology.**—An annual grant of \$25,000 has been given to the University of Minnesota by George A. Hormel and Company, Austin, to establish the Hormel Research Foundation for the promotion of researches in the field of food technology. According to Science, most of the research will be devoted to problems of importance to the packing industry. The work will be carried on by a committee consisting of George O. Burr, Ph.D., Ross A. Gortner, Ph.D., Halvor O. Halvorson, Ph.D., Walter M. Lauer, Ph.D., and Samuel C. Lind, Ph.D. Dr. Lind is chairman.

### NEW YORK

**Free Dispensary Fifty Years Old.**—The Syracuse Free Dispensary celebrated its fiftieth anniversary October 13. Rev. Alphonse M. Schwitalla, dean, St. Louis University School of Medicine, was the principal speaker, on "The Future of Dispensaries." Dr. Charles H. Benson, Bainbridge, for many years head of the dispensary and now retired, was a guest of honor.

**District Meeting.**—The annual meeting of the Fourth District of the Medical Society of the State of New York was held in Amsterdam September 30 and October 1. The speakers included Drs. Lyle A. Sutton, Albany, on "The Menopausal Syndrome"; Stafford L. Warren, Rochester, "Fever Therapy," and William Cook Spain, New York, "The Food Factor in Allergy."

**Society News.**—Forum discussions made up the program of the Onondaga County Medical Society, Syracuse, November 1. Dr. Brooks W. McCuen led a forum on "Cancer of the Rectum and Colon" with Drs. John C. M. Brust and Albert G. Swift as discussers. Dr. Joseph R. Wiseman led a discussion of "Peptic Ulcer," in which the participants were Drs. Clark J. Laus, Donald S. Childs and Percival K. Menzies. Members of the staff of the Syracuse Psychopathic Hospital

presented the program October 4: Drs. Carl A. Whitaker, on "Clinic Treatment of Syphilis of the Central Nervous System" and Eugene Davidoff, "Psychiatric Aspects of the Treatment of Orchidism" and "Play Technic in Children and Juveniles."

### New York City

**Appointments Available at Hospital for Joint Diseases.**—Six house staff appointments on the general service for two years rotating service are available at the Hospital for Joint Diseases, three to begin July 1, 1939, and three to begin Jan. 1, 1940. An examination will be held at the hospital Dec. 29, 1938, for which applicants must register before December 15. The hospital provides maintenance and uniforms. Graduating students and graduates (unmarried men) of class A medical schools are eligible. Applications should be addressed to the Director of the Hospital, Madison Avenue at One Hundred and Twenty-Third Street, New York.

**Position Open for Bacteriologist.**—The Municipal Civil Service Commission announces a vacancy for a bacteriologist. Applicants must have been citizens and bona fide residents of the city for three years. Requirements are an M.D. degree or a Ph.D. degree in bacteriology from an accredited institution, three years' experience in bacteriology, and in addition two years' specialized training in blood grouping and related serologic work or a satisfactory equivalent. Applications will be received until 4 p. m., November 25. Blanks may be obtained by writing to the commission with return postage enclosed. The address is room 1400, Municipal Building, Manhattan.

### NORTH CAROLINA

**Symposium at Duke University.**—More than 500 Southern physicians attended a symposium on medical problems presented by Duke University, Durham, October 13-15 as the first of a series of symposiums celebrating the university's centennial. After the welcoming address by William Preston Few, LL.D., president of the university, Drs. Allen Weir Freeman, Baltimore, and George W. McCoy, New Orleans, spoke on "Public Health Developments in the South" and "Leprosy in the United States" respectively. In the evening there was a discussion of "The Future of American Medicine" by Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, John P. Peters, New Haven, Conn., and Wingate M. Johnson, Winston-Salem. Dr. Milton J. Rosenau, professor of epidemiology, University of North Carolina School of Medicine, Chapel Hill, presided. Addresses were presented Friday morning October 14 by Drs. George H. Whipple, Rochester, N. Y., on "Anemia and the Building of Hemoglobin in the Body" and William H. Sebrell Jr. of the U. S. Public Health Service, Washington, D. C., on pellagra. In the afternoon the speakers were Drs. Charles F. Craig and Edward W. Alton Ochsner, New Orleans, on amebiasis and "The Surgeon's Contribution to Treatment of Amebiasis" respectively. The remaining addresses of the symposium dealt also with tropical diseases: Drs. William G. MacCallum, Baltimore, on "Malaria"; Arturo Lorenzo Carrion, University of Puerto Rico School of Tropical Medicine, San Juan, "Rising Significance of Fungus Infections in Man," and Albert M. Snell, Rochester, Minn., "Tropical and Nontropical Sprue (Chronic Idiopathic Steatorrhea): Their Probable Interrelationship." Dr. James Buren Sidbury, Wilmington, president of the Medical Society of North Carolina, presided at the Saturday morning session.

### OHIO

**The First Lower Lecture.**—The first lecture of a series made possible by the establishment of the Lower Fund was presented by Dr. Oliver H. Perry Pepper, Philadelphia, November 18 in the Medical Library Auditorium, Cleveland, on "Diverticulitis of the Colon." Dr. William E. Lower, Cleveland, endowed the lectureship recently, directing that it deal with some recent development or research but not be confined to any one branch of medicine.

**Personal.**—Dr. John C. Darby, Cleveland, was honored with a dinner September 22 marking his retirement from the 368th Medical Regiment of the Officers Reserve Corps, U. S. Army, of which he had been commander since 1929. He received an honorary life commission as colonel of the regiment. Colonel Darby saw service in the Spanish American War, on the Mexican border and in the World War in France. He was graduated from Western Reserve University School of Medicine in 1900.—Dr. Raymond S. Rosedale, St. Louis, has been appointed pathologist at Mercy Hospital, Canton, to succeed Dr. Max Shaweker.

**Society News.**—The Morgan County Bar Association entertained the Morgan County Medical Society October 11 in McConnellsville. The speakers were Dr. Roy J. Secrest, until recently assistant medical director of the state industrial commission; on the commission and the practicing physician; Mr. R. H. Edwards, claims referee of the industrial commission, on the expert medical witness, and Dr. William E. Masters, on the doctor as a witness.—Dr. Everett N. Collins, Cleveland, addressed the Portage County Medical Society, Ravenna, September 8, on diseases of the colon.—Drs. Charles A. Doan and Bruce K. Wiseman addressed the Columbus Academy of Medicine September 19 on "Advances in the Understanding, Differential Diagnosis and Treatment of the More Common Anemic States" and "Advances in the Diagnosis and Therapy of Thrombocytopenic Purpura" respectively.—Dr. William Bates, Philadelphia, addressed the Montgomery County Medical Society, Dayton, November 4, on "Differentiation Between Visceral and Parietal Pain." Drs. Thomas E. Newell and Miles T. Hoerner addressed the society October 7 on "Etiology and Differentiation of Jaundice" and "Surgical Treatment of Lesions Producing Jaundice" respectively.

### OREGON

**Personal.**—Dr. Thomas L. Meador, Portland, has been appointed in charge of the division of communicable disease in the city department of health.

**New Orthopedic Club.**—Physicians in Portland who limit their practice to orthopedic surgery formed the Portland Orthopedic Club at a meeting October 21. Dr. Otis F. Akin was made president and Dr. Alfred Gurney Kimberley, secretary. Candidates for membership must be diplomates of the American Board of Orthopaedic Surgery.

**The Widmer Research Fund.**—The University of Oregon Medical School, Portland, has received a gift of 171.67 acres of land near Eugene valued at about \$30,000, the income from which is to be devoted to research in cancer and heart disease. The property was conveyed by Misses Gertrude and Margaret Widmer, Eugene, in memory of their parents and of two brothers who graduated from the university. The gift will be established as the Widmer Memorial Research Fund.

**Annual Registration Due December 1.**—All practitioners of medicine and surgery holding licenses to practice in Oregon are required by law to register annually on or before December 1 with the secretary of the Board of Medical Examiners and at that time to pay a fee of \$5. A practitioner failing to register is subject to a penalty of \$1 for each thirty days or part thereof of default, and his failure to reregister within ninety days after December 1 is a misdemeanor.

### PENNSYLVANIA

**Society News.**—A symposium on typhoid fever was presented before the Fayette County Medical Society, Uniontown, November 3, by Drs. Charles H. Smith, Herbert Lund and John B. Hibbs, all of Uniontown, and Paul A. Keeney, Harrisburg.—Dr. Morris A. Silver, Harrisburg, addressed the Dauphin County Medical Society, Harrisburg, November 1 on "Recognition of the Commoner Anorectal Diseases and Their Treatment."—Dr. Daniel Murray Angevine, New York, addressed the Harrisburg Academy of Medicine recently on arthritis.—Dr. Albert F. Doyle, Johnstown, addressed the Montour County Medical Society, Danville, October 21 on "Public Health Duties of the Physician Treating Syphilis."

### Pittsburgh

**Auxiliary Holds Annual Institute.**—The Woman's Auxiliary of the Allegheny County Medical Society held its annual health institute at the William Penn Hotel November 1. Dr. Paul Titus gave an address on maternal conditions in the United States, followed by a showing of the "Birth of a Baby." Dr. Chauncey L. Palmer, chairman of the committee on public health legislation of the state medical society, spoke on "Health Legislation—What State Medicine Means to You." Mrs. Joseph P. Dobo spoke on "State Medicine as I Knew It in Vienna." Dr. John N. Frederick discussed "Mental Diseases with Special Reference to Causes and Prevention," and Dr. William H. Guy presented an illustrated lecture on syphilis.

**Society News.**—Dr. Claude S. Beck, Cleveland, was the guest speaker before the Allegheny County Medical Society November 15 on "Heart Surgery." A. L. Murray of the U. S. Bureau of Mines, Pittsburgh, addressed the society October 18 on "Carbon Monoxide Poisoning" and Dr. Moses Paulson, Baltimore, "Diarrheas and Dysentery of the Adult

—Practical Aspects of Diagnosis and Treatment." The scientific exhibit was presented by the Bureau of Mines. There was also a discussion on "Reaching the Ear of the Health and Tax Conscious Public Through the Membership of the County Medical Society and Its Woman's Auxiliary" by Mrs. Augustus S. Kech, Altoona, chairman of the public relations committee of the Woman's Auxiliary to the Medical Society of the State of Pennsylvania. Other speakers were Drs. Chauncey L. Palmer, chairman of the committee on legislation of the state medical society; Charles H. Henninger, president-elect, and Mrs. Walter F. Donaldson, Pittsburgh, president of the Woman's Auxiliary of the state medical society; all are of Pittsburgh.—Drs. George Booth and Karl Zimmerman addressed the Pittsburgh Academy of Medicine October 25 on "Hypoglycemia" and "Oil Soluble Anesthetics in the Treatment of Anal Ulcer" respectively.

### TENNESSEE

**District Meeting.**—Guest speakers at the annual meeting of the Third Councilor District of the Tennessee State Medical Association in Chattanooga, September 29, were Drs. Hugh H. Trout, Roanoke, Va., on "Some Mistakes in the Diagnosis of Acute Appendicitis" and "Treatment of Carcinoma of the Breast"; Axel N. Arneson, St. Louis, "Carcinoma of the Cervix" and "Carcinoma of the Uterus," and John B. Youmans, Nashville, "Less Common Manifestations of Coronary Thrombosis" and "Recognition of Cardiac Arrhythmias by Simple Physical Examination."

### VIRGINIA

**Special Society Elections.**—Several special societies held their annual meetings in Danville during the annual session of the Medical Society of Virginia in October. The Virginia Orthopedic Society elected the following officers: Drs. Roy M. Hoover, Roanoke, president; Henry H. Wescott, Roanoke, vice president, and Bernard H. Kyle, Lynchburg, secretary, reelected. Dr. William W. Waddell Jr., Charlottesville, was elected president of the Virginia Pediatric Society; Dr. Leta J. White, Petersburg, vice president, and Dr. John M. Bishop, Roanoke, reelected secretary. At the meeting of the Virginia Obstetrical and Gynecological Society the following were elected: Drs. Charles J. Andrews, Norfolk, president; Harry Hudnall Ware Jr., Richmond, vice president, and Richard B. Nicholls, Norfolk, secretary. The Virginia Radiological Society reelected Drs. Frederick M. Hodges, Richmond, president, and Vincent W. Archer, Charlottesville, secretary. Dr. Lawrence T. Price, Richmond, was elected president of the Virginia Urological Society; Drs. Albert A. Creecy, Newport News, and Linwood D. Keyser, Roanoke, vice president and secretary respectively.

### WASHINGTON

**State Program for Crippled Children.**—During the first two years of the state crippled children's program conducted by the Washington State Department of Social Security with state and federal funds, 1,940 children have attended clinics. These clinics have been held at intervals of six months in six centers, and twenty-three orthopedic and plastic surgeons have assisted in them. Of the children, 731 have been referred to the state agency and 309 to private orthopedic units for treatment. The staff surgeons elected from their group seven men to serve as a committee to review cases referred to the crippled children's program and assign them for treatment to the staff surgeons in the hospital center nearest each child's home. The social workers in the hospital centers cooperate in arranging convalescent care and educational facilities. If the child when discharged from orthopedic treatment is of the age of employment but not equipped to enter private industry, he is referred to the state department of vocational rehabilitation for possible training and placement. Since September 1935 the state has spent \$118,730.96 in the program and the Children's Bureau contributed \$109,354.82.

### WISCONSIN

**Society News.**—Drs. Stanley R. Maxeiner and Henry E. Michelson, Minneapolis, addressed the Barron-Washburn-Sawyer-Burnett County Medical Society in Rice Lake, October 4, on "Surgery of the Stomach and Duodenum" and "Diagnosis and Treatment of Common Skin Diseases" respectively.—Dr. Raymond G. Arveson, Frederic, president-elect of the State Medical Society of Wisconsin, addressed the Chippewa County Medical Society, Chippewa Falls, October 25, on "Adequacy of Medical Care."—At a meeting of the Grant County

Medical Society, Lancaster, October 25 the speakers were Drs. John C. Grill, Milwaukee, on "Importance of the Laboratory in the Diagnosis of Blood Diseases"; Elmer L. Sevringhaus, Madison, "Menopause and Irregular Menstruation," and George H. Ewell, Madison, "Interesting Urological Cases." Mr. J. George Crownhart, executive secretary of the State Medical Society of Wisconsin, Madison, reported on his recent study of sickness care in Europe.—Dr. Henry W. Meyerding, Rochester, Minn., addressed the Kenosha County Medical Society, Kenosha, September 22 on recent advances in orthopedics.—Dr. James M. Hayes, Minneapolis, addressed the La Crosse County Medical Society October 12 on "Acute Abdominal Surgery" and Dr. Albert E. Rector, Appleton, president of the state medical society, discussed "Present Day Trends in Medicine."

### GENERAL

**Examinations in Pediatrics.**—The American Board of Pediatrics announces that its 1939 examinations will be held April 26 in New York, May 16 in St. Louis, and November 14-15 in Cincinnati. Appointments for the April examinations must be made by December 26, for the May one by Jan. 16, 1939, and for the November one by July 14. The secretary is Dr. Charles Anderson Aldrich, 723 Elm Street, Winnetka, Ill.

**The Lilly Award in Biologic Chemistry.**—Nominations are invited for the Eli Lilly and Company Prize in Biological Chemistry to be awarded by the American Chemical Society at its spring meeting. The prize, established by the Lilly firm in 1934, is \$1,000 with a bronze medal and \$150 or as much thereof as is needed to defray the expenses of the recipient to the meeting. A nominee must not be over 35 years old on April 30 of the year of the prize and shall have accomplished outstanding research in biologic chemistry, working in a college or university. For the purpose of this award biologic chemistry does not include immunology, clinical investigation, pharmacology or experimental therapeutics. It is intended for persons on the threshold of their career and will not be judged in comparison with the work of more mature and experienced chemists. Nominations must be received before Jan. 5, 1939. They should be sent directly to the secretary of the American Chemical Society, Charles L. Parsons, Mills Building, Washington, D. C.

**Bequests and Donations.**—The following bequests and donations have recently been announced:

Christ Church Hospital, Philadelphia, \$7,800 by the will of Sarah L. Bailey.

Fitzgerald-Mercy Hospital, Darby, Pa., \$5,000 by the will of the late Mrs. May Neff Fitzgerald Major, whose first husband bequeathed funds for the erection of the hospital; Children's Seashore Home, Atlantic City, N. J., also received \$1,000.

Mount Sinai Hospital, New York, \$10,000 by the will of the late Mrs. Carrie L. Lehman.

Methodist Episcopal Hospital, Indianapolis, \$10,000 by the will of Lulu E. Critz, Anderson, Ind., who died June 29.

American Society for the Control of Cancer, New York, \$10,000 by the will of Miss Katherine Rhoads, Richmond, Va., to be used in Virginia.

Hamot Hospital Association, Erie, Pa., and Wills Hospital, Philadelphia, \$1,000 each by the will of Frank B. Rutherford.

Mansfield General Hospital, Mansfield, Ohio, \$25,000 from the estate of the late Richmond Smith.

Lake County Memorial Hospital, Painesville, Ohio, \$5,000 from the estate of the late Clifton N. Windecker.

Bronson Methodist Hospital, Kalamazoo, Mich., \$100,000 from the Kresge Foundation to be applied on a new addition.

The city of Coshocton, Ohio, will receive about \$225,000 from the will of Ernest A. Bachert, to be held in trust for ten years and to be expended at the end of that period for the erection and maintenance of a hospital for crippled children.

Harrisburg Polyclinic Hospital, Harrisburg, Pa., \$350,000 by the will of the late Daniel M. Dull in memory of his father.

**Society Elections.**—Dr. James R. McCord, Atlanta, Ga., was chosen president-elect of the American Association of Obstetricians and Gynecologists at the recent annual meeting and Dr. James E. King, Buffalo, was installed as president-elect. Dr. James K. Quigley, Rochester, N. Y., was elected vice president and Dr. James R. Bloss, Huntington, W. Va., was reelected secretary. The next meeting will be held in Hot Springs, Va.—Dr. Harold D. Corbusier, Plainfield, N. J., was elected president of the Academy of Physical Medicine at the annual meeting in Washington, D. C., in October. Drs. Fred H. Albee, New York, and William H. Schmidt, Philadelphia, were elected vice presidents and Dr. Herman A. Osgood, Boston, was elected secretary.—Dr. Russell H. Oppenheimer, Atlanta, was chosen president-elect of the Association of American Medical Colleges at its annual meeting in Syracuse, N. Y., October 24-26, and Dr. Willard C. Rappleye, New York, was installed as president. Dr. Waller S. Leathers, Nashville, Tenn., was elected vice president and Dr. Fred C. Zapffe, Chicago, reelected secretary. The next meeting will be held in Cincinnati, Oct. 23-25, 1939.

**Radiological Society of North America.**—The annual meeting of the Radiological Society of North America will be held in Pittsburgh November 28-December 2 with headquarters at the William Penn Hotel. This year the society is sponsoring its first refresher courses, which will be given November 27-28 in the physics of radiation, radiology of the chest, radiology of the gastrointestinal tract, pathology of tumors, radiology of bone tumors, roentgen analysis of fractures, and radiology of sinuses and mastoids. Much of the scientific program is in the form of symposiums. Among the speakers will be:

Drs. Marcy L. Sussman and Leopold Jachas, New York, Bone Changes in Generalized Lipoid Diseases.

Drs. Ross Golden and Paul C. Swenson, New York, Experiences with the Compression Technic in Gastrointestinal Examinations.

Dr. Milton Friedman, New York, The Relation of Ovarian Hormones to Benign Breast Hyperplasia and Neoplasia.

Dr. Vincent C. Johnson, Ann Arbor, Mich., The Value of Roentgen Examination of the Paranasal Sinuses.

Drs. David E. Ehrlich and Arthur B. Robins, New York, Group X-Ray Surveys of Apparently Healthy Individuals.

Dr. Herman A. Osgood, Boston, Treatment of Acute and Chronic Inflammatory Conditions by Fractional Doses of X-Rays.

Dr. John D. Camp, Rochester, Minn., Experiences with Lipiodol in the Localization of Lesions Associated with Low Back and Sciatic Pain.

Dr. Arthur U. Desjardins, Rochester, Minn., Roentgen Therapy for Chronic Infectious Arthritis.

Dr. Hugh M. Wilson, New Haven, Conn., Exploration of the Thorax with Body Section Roentgenography.

Dr. Henri Coutard, Chicago, Present Conception of Treatment of the Larynx.

**Changes in Status of Licensure.**—The Ohio State Medical Board recently reported the following action:

Dr. Charles R. Buck, Cincinnati, license restored July 19.

Dr. Ralph Bernard Brown, Columbus, license restored April 5.

The New York State Board of Medical Examiners has recently reported suspension of licenses of the following physicians on the basis of fraud and deceit:

Dr. Isadore Roth, Brooklyn, one year from June 17.

Dr. Benjamin M. Wax, New York, one year from June 17.

Dr. Peter Kleinkopf, New York, eight months from June 17.

Dr. Isidore E. Kaplan, New York, one year from June 17.

Dr. Harry Grodzicker, Brooklyn, one year from June 17.

Dr. Max Ehrenberg, New York, one year from June 17.

Dr. Jacob R. Firneno, Brooklyn, six months from June 17.

The state board of medical education and licensure of Pennsylvania recently reported the following:

Dr. Arthur H. Gaston, Pittsburgh, license revoked for unethical conduct.

Dr. Harry Emerson Gray, Zelienople, license revoked for unethical conduct. It is said that although he had been a general practitioner for many years he posed as an eye specialist for an optical company.

The state department of registration of Utah reports the following action:

Dr. Afton M. Livingston, Ogden, license suspended August 1 for unprofessional conduct; to be reinstated in one year on condition that he complete a graduate course in a medical college.

The Florida State Board of Medical Examiners reports the following:

Dr. Roy Webb, Delray Beach, license restored June 13.

## Government Services

### Examination for Position of Toxicologist

The U. S. Civil Service Commission announces that an open competitive examination will be held for the position of principal industrial toxicologist (organic compounds) in the U. S. Public Health Service at a salary of \$5,600 a year. The duties will be to serve as scientific head of a section of industrial toxicology, studying the relation between chemical composition and pharmacologic action of organic compounds, and to be responsible for the planning and direction of scientific research and routine work in the industrial toxicology of organic compounds. Candidates must have graduated with an M.D. degree from a medical school of recognized standing and must not have passed their fifty-third birthday on the date of the close of applications. Applications and further details may be obtained from the Secretary, Board of U. S. Civil Service Examiners, at any first class post office, from the commission at Washington, D. C., or from the district office of the commission in any of the following cities: Atlanta, Boston, Chicago, Cincinnati, Denver, New Orleans, New York, Philadelphia, Seattle, St. Louis, St. Paul, San Francisco, Honolulu, Balboa Heights, St. C. Z., and San Juan, P. R. The closing date for applications is November 28, if received from states other than Arizona, California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington and Wyoming. For the Far Western states the date is December 1.

Oct. 22, 1938.

#### Action of Ephedrine in Acute Pancreatitis

At the July 8 meeting of the Société médicale des hôpitaux of Paris, a paper was read by Dr. P. Jacquet and his associates on three cases presenting a syndrome commonly observed in the initial stage of an acute pancreatitis. The existence of such an acute pancreatitis was verified at operation in two of the three cases. The clinical picture was identical, the noteworthy features being severe epigastric pain radiating toward the back, which could not be relieved by relatively large doses of morphine. The patients were pale and appeared to be in a state of shock with only slight increase in the pulse rate and no change in the blood pressure. There was a noticeable increase in the blood sugar content and a marked glycosuria in one patient. Ephedrine was given to all four patients to combat the symptoms of shock. In the first case 0.04 Gm. was given daily for three days and was followed by considerable relief of the pain. This patient was operated on successfully later for a hemorrhagic cyst of the pancreas. In the second case the symptoms of acute pancreatitis were accompanied by a hemorrhagic pleurisy. After a few days administration of 0.08 Gm. daily of ephedrine hydrochloride the abdominal pain, shock and pleurisy disappeared, but the pain recurred as soon as the ephedrine was discontinued. After the first dose was repeated the pain ceased. This patient was given a total of almost a gram of ephedrine hydrochloride in twenty-five days and never had a recurrence of symptoms during a year of observation. The third patient was given 0.04 Gm. of ephedrine hydrochloride in a single dose six hours after the onset. The pain and symptoms of shock disappeared but recurred two hours later. A second injection was given thirteen hours after the onset and again gave relief for two hours. A suprapubic incision revealed a hemoperitoneum but the patient's condition did not permit exploration of the upper portion of the abdomen. Recovery followed and no relapse was observed during the next three months. The conclusions based on these observations were that, before the irreparable lesions incident to an acute pancreatitis appear, there is a vascular disturbance on which such factors as the pharmacodynamic action of ephedrine, the shock of an operative intervention or perhaps a general anesthesia seem to have an inhibitory action. Ephedrine ought to be given in much larger doses in acute pancreatitis than in collapse or surgical shock. In the discussion, Dr. Gilbert-Dreyfus cited a case in which operation based on the diagnosis of acute peritonitis revealed an edema of the pancreas. Following the operation, repeated emesis and a poor general condition but no signs of circulatory collapse were noted. The patient was given 0.06 Gm. of ephedrine hydrochloride followed by complete transformation of the clinical picture after the fourth injection. Dr. Donzelot believed that pancreatic lesions were not always responsible for such a severe syndrome. The striking features in the pancreaticosolar syndrome were severe lumbar pain and very marked symptoms of shock.

#### Prolongation of Effects of Tetanus and Diphtheria Antitoxins

Prof. G. Ramon of the Pasteur Institute of Paris has studied the action of tetanus and diphtheria toxoids since his discovery of both these toxoids about ten years ago. At the July 8 meeting of the Société médicale des hôpitaux of Paris, Prof. Ramon and associates presented the results of the comparative effects of these toxoids in the form of two papers. They recalled their experience in the combined use of the tetanus

antitoxin and toxoid in vaccination against tetanus, a method now obligatory in the French army. The person to be vaccinated is given in two different places of the body a dose of the serum, for adults, representing from 10 to 20 thousand antitoxic units and another of 1 cc. of tetanus toxoid. Fifteen days later, 2 cc. of the toxoid is given and again three weeks after the second dose a third one of 2 cc. of the toxoid. The immunity conferred by the antitoxin is thus greatly prolonged. This combined use of the tetanus antitoxin and toxoid was utilized in the treatment of four cases of injuries as a prophylactic measure, the theory being that the serum, owing to its high titer in antitoxic units, had a better immediate protective action but that, because such action was only transitory, it could be prolonged by giving the tetanus toxoid. Each patient received a dose of the serum corresponding to 150,000 units and at the same time he was given 2 cc. of the tetanus toxoid. Later on, doses of 3, 4 and 5 cc. of the toxoid were given at intervals of a few days. Determinations of the antitoxin content of the blood made at various periods showed that it was possible to prolong the passive immunity conferred by the antitoxic serum, which is only of brief duration, by the active immunity due to the toxoid, which after repeated injections becomes more and more permanent. The great advantage of such a combined use of the antitetanus serum and tetanus toxoid is that not only will it be possible to avoid, in the future, the continued administration of large doses of the serum to prevent a late tetanus but the antitoxin units in the blood will be maintained at a sufficiently high titer, when the passive but transitory action of the serum is prolonged, through the active immunizing action of the toxoid. Up to the present, no untoward effect of the use of the toxoid has been reported.

In the second paper Professor Ramon discussed the first results of combined use of diphtheria antitoxin and toxoid. Although the use of the diphtheria antitoxin had revolutionized the treatment of the disease, the effects of the antitoxin in diphtheria conferred only a passive immunity of relatively short duration, so that it has become necessary to repeat the injections in order to prevent serious complications and recurrences. The object which Ramon had in mind in advocating the combined use of the diphtheria antitoxin and toxoid was to avoid giving additional doses of the former. Two injections are given in different parts of the body, one of a massive dose of the antidiphtheria serum, in general from 1,000 to 2,000 units per kilogram of weight, according to the severity of the case, a total of from 10 to 60 thousand units except in very grave cases, in which a dose of 80 thousand units is given. The dose of diphtheria toxoid should be 0.1 cc., representing 150 units. Following this large initial dose of the diphtheria antitoxin, the toxoid is injected at intervals of five days in progressively increasing doses, beginning with 1 cc., then 2 cc., 3 cc. and so on. This technic has been used by various clinicians in 120 cases of diphtheria with but slight reactions to be ascribed to the injections of the toxoid. Only three slight and transitory paralyses of the soft palate have been observed. A study of the titer of antitoxin units in the blood of these patients has shown that the transitory passive immunity conferred by the diphtheria antitoxin is converted into a prolonged active immunity as the result of the action of the toxoid.

In the discussion of the second paper, fifteen cases treated by this method were reported by Professor Debré and Dr. Mallet, who stated that their observations as to the transition from a passive immunity of short duration conferred by the diphtheria antitoxin to the prolonged active immunity conferred by the anatoxin entirely corroborated the report made by Professor Ramon. The number of cases, only fifteen, thus far treated was too small on which to base any opinion. Although no postdiphtheritic paralysis had been observed, the cases had been of a mild type. The allergic reactions due to the use

of the toxoid had been slight. Dr. Marquezy doubted whether Ramon's method offered any real advantages because nearly all patients who have been given the antitoxic serum show a protective titer of antitoxic units in the blood. The most important question in the treatment of diphtheria was to create as large a number of antitoxic units in the blood as possible and at as early a stage as it could be accomplished.

#### Basal Metabolism in Leukemia and Splenomegaly

Two papers on basal metabolism in leukemia and splenomegaly were read at the July 8 meeting of the Société médicale des hôpitaux by Drs. Emile Weil, hematologist, and A. Aschenasy. In fifteen cases of leukemia, five of which were of the myelogenous and ten of the lymphatic type, a persistent increase in the metabolic rate, which varied from 50 to 60 per cent, was observed in all the patients. This increase is independent of the number of red blood cells and the percentage of immature forms of red blood cells as well as of the size of the spleen or of the lymph nodes. The increased rate of basal metabolism is the expression of the entire leukopoietic process of the organism. A severe concomitant anemia appears to counteract the effects of the leukemia by lowering the metabolism rate. Although the latter may not have any prognostic value in the leukemias, it is of diagnostic interest in the cryptoleukemias involving the lymph nodes or spleen, in which the metabolic rate is constantly high. They had never observed any beneficial influence from irradiation of the thyroid.

As to the metabolic rate in splenomegaly, only a slight increase was noted in four cases of congenital hemolytic icterus, but a more marked increase in hypertrophic cirrhosis of the liver with splenomegaly. In three cases of Gaucher's disease and even in most cases of isolated splenomegaly, especially those of tuberculous or syphilitic origin, the metabolic rate was found to be about normal as opposed to the increased rate found in splenic cryptoleukemias and in splenohepatomegaly as observed in the erythroblastic form of adults. The rate was considerably increased in both of these types of blood disease. Whenever a high metabolic rate is accompanied by splenomegaly without icterus or acute posthemorrhagic anemia, the clinician must keep in mind the possible existence of a leukemia or of an erythroblastosis. Following splenectomy, a decrease of the metabolic rate was observed in three of four patients and an increase in a fifth one. The authors were of the opinion that the spleen has a constant influence on the metabolic rate but that this influence is subject to variations in individual cases.

#### The Pathology of Poliomyelitis

Dr. Peters of Munich had the opportunity to study the central nervous systems of thirty-nine persons who had died of poliomyelitis in 1937. Poliomyelitic changes were observed in the anterior horns of the spinal cord, in the lateral and posterior horns, in the region of the sensory and vegetative nuclei of the medulla and the pons, in the mesencephalon, in the hypothalamus, in the cerebellum and in various parts of the cerebral cortex (ascending frontal convolution, parietal cortex, insular cortex). In the ascending frontal region pathologic changes had occurred in all the layers, not merely in the third, fourth and fifth layers. In a few cases circumscribed foci, confined to the molecular layer of the frontal central cortex, were observed. Alterations were present throughout the central nervous system: ganglion cells were destroyed and glial-mesodermal infiltrates had formed. The degeneration of ganglion cells was most remarkable in the frontal horns of the spinal cord. In the cadavers studied the substantia nigra was relatively free from pathologic processes; in only a few instances had destruction of ganglion cells taken place therein. This observation is of twofold practical signifi-

cance: first, it is important to the anatomist for differential diagnosis of poliomyelitis and lethargic encephalitis (Economo) and it is important to the clinician, as he need not fear in general the manifestation of parkinsonian symptoms in persons who have recovered from poliomyelitis. In several cases thick glial-leukocytic infiltrates were found in the pons and in addition a deficiency of ganglion cells at the base of the pons in the vicinity of the pontile nuclei and the area of the pyramidal tract. These foci, together with foci in the ascending central region of the cerebral cortex, can through stimuli or trophic disturbances in the first motor neuron lead to spastic symptoms such as exaggerated reflexes. The latter symptom is more often determined in clinically examined cases. In three cadavers a manifest preponderance of pathologic changes in the brain, especially in the pons and medulla, as contrasted with the spinal cord, were noted. It may be assumed therefore that some cases of poliomyelitis, at least in the initial stage, present only lesions in the cerebral nerves, whereas not the slightest degree of paralysis is present in the region of the extremities; under certain circumstances spastic symptoms may even appear. In a few cases also more or less extensive primary foci were observed in the white substance of the spinal cord. The meningeal lesions, which in some instances consisted of a pronounced maculating, leukocytic meningitis, were interpreted as a primary reaction to poliomyelitis virus and its toxin. An interdependence of the meningeal changes and those in the nerve tissue does not exist; it is a question of coordinated processes. The wide distribution of the pathologic changes in poliomyelitis argues against use of the designation "poliomyelitis anterior." Heine-Medin disease is a myelo-encephalomeningitis which cannot rightfully be qualified by the adjective "anterior."

#### Sugar and the Teeth

Dr. Wolinz discusses the interrelation of sugar and the teeth in the *Zahnärztlichen Mitteilungen*. Statistics have revealed the astonishing fact that Germany, although a large producer of beet sugar, ranks fifth among the nations as a consumer of sugar. The view that sugar damages the teeth is no longer tenable on the basis of recent observations. Laboratory experiments as well as observations *in vivo* show that raw sugar and even mixtures of raw sugar and fat (whipped cream, marchpane) and protein exert no corrosive effect on the dental enamel. The injurious effect of neutral yeasty bakery goods can be favorably offset or abolished by ingestion of fruits and vegetables or salads. Carbohydrate ingested in the form of sugar ferments not at all or only as lactic acid. On the contrary, carbohydrate decomposes if ingested in the form of starches; it is first decomposed into sugar by the oral secretions and then undergoes further changes which exert a more harmful influence on the dental enamel than lactic acid. Dental caries among bakers is a special instance; particles of flour and sugar are inhaled in the course of the work; these particles light on the front teeth, and the deposits on the upper jaw in particular are not carried away by the saliva. Workers in sugar are consistently free from sugar caries.

#### Prof. Johannes Lange Is Dead.

With Prof. Johannes Lange, ordinarius in psychiatry at Breslau, passes at the age of 47 one of the finest of the younger German psychiatrists. Lange was a pupil of Kraepelin in the best sense of the word; he was loyal to his teacher and possessed the latter's eagerness for achievement. Lange's energetic pursuit of research and his remarkably able presentation of material quickly smoothed the path of his academic career; at the age of 40 he was already ordinarius. In addition to his particular specialty, Lange concerned himself professionally with cerebral pathology and genetic research and contributed notably to those fields. One has only to recall his research on twins, studies which resulted in the volume "Crime as Destiny," Precisely in this controversial field of genetic research, in which at present

so many differently minded elements are mixed, Lange has accomplished much good through public criticism of exaggerations and spurious representations, no mean task in view of the difficult situations often encountered in this field today.

#### Prophylaxis of Gas Gangrene

A material suitable for immunizing man against gas gangrene due to *Bacillus welchii* has been described by Penfold and Tolhurst at the Baker Institute, Melbourne. These workers have previously described the immunization of animals with alum-precipitated formaldehyde toxoid made from *Bacillus welchii* toxin, and their experiments with animals have been so successful that in August 1937 it was decided to use the vaccine in man. An eighteen hour culture of *Bacillus welchii* grown in anaerobic veal broth containing 0.1 per cent of dextrose was filtered through a Seitz bacterial pad and the minimum lethal dose of the filtrate was determined intraperitoneally in mice. About 0.4 per cent of solution of formaldehyde was added to a freshly prepared toxin and the mixture was incubated at 37 C. for six or seven days, until the toxicity was so reduced that 1 cc. would not kill mice weighing 20 Gm., while 5 cc. would kill rats weighing 100 Gm. The toxoid was precipitated with an 8 per cent solution of alum and the immunizing power of the material was tested in guinea pigs. The first human subject received 0.25 and 0.5 cc. subcutaneously, with an interval of four weeks between the doses. The reactions were mild and restricted to the site of inoculation. Further injections in different persons with doses up to 1 cc. caused no serious reactions. Examination of immunity response showed that this alum-precipitated *Bacillus welchii* toxoid given in two or three injections stimulated the production of antitoxin in all the persons injected. To demonstrate that the immune human serum was fully protective against living *Bacillus welchii* culture, passive immunity experiments were carried out in mice. It was found that the protected mice withstood at least two minimum lethal doses of culture. It has not yet been determined what level of antitoxin is fully protective or what is the duration of the immunity in man.

#### Physical Fitness Campaign

Australia has lagged behind certain other countries in attempting to improve the health and physique of her people by engaging in an intensive campaign of public education in physical fitness. It is encouraging that several of the state governments have taken steps this year in such a direction. At a meeting of the delegates from sporting bodies with a commonwealth-wide representation held in Sydney following this year's Olympic Games, it was agreed that there was urgent need for a fitness campaign in Australia. This feeling coincides with a similar development in medical and scientific circles, and plans for the institution of such a campaign is now under consideration in most states. One difficulty is the scarcity of qualified instructors who are fully acquainted with modern methods in physical training now in practice abroad. A welcome indication of progress is the appointment of a Canadian expert to the position of director of physical education in New South Wales, which state is furthest advanced in the fitness movement. Its government has appointed a physical education advisory committee to recommend methods adapted to local circumstances and the character and ideals of the community which can be adopted in New South Wales. It is hoped that sporting organizations, medical societies and other scientific bodies will cooperate fully in this movement which has found life in Australia this year. Fortunate as we are in the matter of low death rates and facilities for enjoying

the benefits of open air games, there is manifest scope for the avoidance of much sickness which would yield to a better understanding by the people of the functioning of their bodies.

#### Insurance Difficulties in New Zealand

New Zealand, as well as Australia, is experiencing some difficulty over the question of cooperation between the medical profession and the government on matters pertaining to health insurance. The British Medical Association in New Zealand, feeling that the government's proposed scheme for a universal practitioner service offered no appreciable advantage over the system that obtains at present, submitted to the government an alternative scheme for a more complete service based on income limits. The New Zealand government rejected this scheme, and as a result the association has broken off all discussions with the government. This difficulty with the medical profession is not the only problem met by the government in its attempt to introduce its social security plan. For several months a special committee has been investigating financial aspects of the whole scheme, without reaching any satisfactory decisions.

#### Tests of the Milk Supply

The announcement that, in future, regular monthly bacteriologic tests will be made of Melbourne's milk supply marks a progressive step in the development of Australia's public health activities. This is the first regulation of its kind in Australia. Under the plan, milk from every farm supplying the metropolitan area will be subjected to a test once a month. The work will be carried out by officers of the department of agriculture, the cost being met by the milk board. These tests will give metropolitan consumers definite assurance of a clean and safe milk supply, and it is expected that this assurance will stimulate the consumption of milk—a result desirable from the medical as well as the producers' standpoint, as the consumption of milk in Australia, notwithstanding the fact that dairying is one of its most important industries, is far below an adequate requirement for optimal health.

#### Gift for China

The Australian government has provided 500,000 doses of anticholera serum as part of a world gift of 6,000,000 doses to aid China in fighting her present epidemics of cholera. The serum was prepared by the commonwealth laboratories and is valued at approximately £4,000.

#### Death of Sir Colin MacKenzie

The death of Sir William Colin MacKenzie, M.D. (Melbourne), F.R.C.S. (Edinburgh), F.R.S. (Edinburgh), the founder and first director of the Australian Institute of Anatomy at Canberra, means a definite loss to the medical profession of Australia. Sir Colin belonged to that small band of Australian medical men whose work and writings are known beyond the confines of our island continent. He had a most unusual professional career, graduating as a comparative anatomist from the ranks of general practitioners of medicine. One of his earliest studies was on syphilitic dactylitis, and for two years before Schaudinn's momentous discovery of the spirochete of syphilis he urged the officers of the bacteriologic department of the University of Melbourne to collaborate with him in a search for the causal organism. During his first visit to Europe in 1904, MacKenzie was greatly influenced by the principles of muscle rest and muscle recovery then finding a place in orthopedic treatment. On his return to Melbourne the treatment of the recent and remote effects of infantile paralysis on children was the master idea in his mind. He gradually evolved his theories relating to the fascinating subject of muscle reeducation. These slowly took shape until they were ultimately embodied in his textbook "The Action of Muscles, Including Muscle Rest and Muscle Reeducation." Although commonplace today, MacKenzie's original concep-

tions were then revolutionary. He was the first to use the special term "muscle reeducation" and to stress the importance of the action of gravity in all educational attempts to regain muscle function after paresis of any nature. The minimal load, the zero position, the smooth powdered surface of board or cardboard for reeducational muscle work must always be associated with his name. While an orthopedic surgeon he found time to investigate the special anatomic problems associated with native fauna in Australia. These dissections helped him to correlate function and structure in muscles and to develop treatment for paralyzed muscles accordingly. After the great war MacKenzie devoted himself more and more to comparative anatomy, and his collection of Australian faunal specimens eventually became too great for any private individual. The commonwealth government acquired the collection as a gift to the nation in 1924. Subsequently William Colin MacKenzie received the honor of knighthood. In 1930 the collections were transferred to Canberra and have since been housed, with many additional gifts, in the two spacious museums attached to the Australian Institute of Anatomy. Here, as director, Sir Colin spent the remainder of his working life. His services to Australia will become of more and more importance as research workers of the future make use of the material that he made available to them.

### BELGIUM

(From Our Regular Correspondent)

Oct. 8, 1938.

#### Benzenes, Benzines and Industrial Safety

Mr. A. Stassens has had published in *Industrie chimique belge* a noteworthy report on the medical aspect of the problem of benzenes ( $C_6H_6$ , or benzol), benzines (European industry calls the American "gasoline" also "benzine") and industrial safety; a discussion of all aspects, chemical, technical, professional, of the industrial use of hydrocarbons is included. Around 1936 a large number of serious cases of benzene poisoning were reported in various Belgian industries. Following these incidents, investigations were begun and Mr. Stassens collected a great deal of interesting information. The first part of the report is devoted to the benzene compounds (production, rectification, properties, utilization, methods of analysis). All relevant practical data with regard to the toxicity of these products is set forth. The second part of the report deals with the "benzines," substances which are still all too frequently confused with the benzene compounds. The author discusses the production of benzines, the refining process, the physical and chemical determinations used in analyses, the toxicity. All these points are the object of a detailed and careful study. In a third section of his report, Stassens discusses the problem of those closed chain compounds which, by their presence in essences of petroleum, impart formidable toxic properties to the latter. An appendix to the report contains the texts of all pertinent legislation. Physicians will read with interest this clear, complete and accurate portrayal of the contemporary question of hydrocarbons. They will simultaneously become convinced of the complex nature of the problem and of the need for active participation of doctors, as well as industrialists and workers, in the protection of that ever increasing number of persons in industry who are exposed to this particularly serious and fearful type of poisoning.

#### Yellow Fever in the Belgian Congo

Dr. Van Campenhout recently published a study on yellow fever in the Belgian Congo. A continuous and energetic crusade against *Aedes aegypti*, which is the main transmitting agent of the virus in epidemics in urban centers, is carried on. The sanitary conditions have been improved to such an extent in Matadi that the use of mosquito netting is no longer necessary. The examination of samples of liver tissues which were taken from cadavers in all suspected cases of yellow fever has not given, up till now, confirmation of the presence of the dis-

ease. Further examinations will be made on tissues taken from viscerotomy in new cases. Reports have been made on the communications recently passed to the International Office of Public Health. The head physician of the colony has not believed it his duty, up till now, to encourage the administration of anti-yellow fever vaccines although some volunteers asked to have them administered. There are many donors of immunizing serum. Disinfection of air ships in the Belgian Congo by the use of pyrethrum preparations has given satisfactory results. Fumigations are made just before embarkment and departure of the ship. The sanitary aerodromes of Leopoldville and Coquilhatville are provided with means against yellow fever. Elisabethville, Libenge and Boma aerodromes can be provided for this purpose in a few days if necessary.

### Professional Secrecy

An interesting discussion of professional secrecy was made by Dr. Heger in the Société de médecine légale of Belgium. The author called to mind a series of authoritative opinions with regard to the ethics to be maintained by physicians who also serve as officials of public or private organizations. He summarized his own views by saying that professional secrecy is unqualifiedly *de rigueur* for the practitioner who serves in an official capacity. The attending physician may furnish a certificate to a patient on request, but he is under no compulsion to do so. Dr. Ilivier asked the society's opinion on the following point: A medical expert is appointed by a court of law to ascertain the cause of death in an industrial accident case. For the fulfilment of his mission he must be in possession of all pertinent facts. Ought the attending physician to communicate his medical record of the accident victim to the medical examiner? Dr. Duvoir formally replied in the negative and cited a 1913 decision of the Court of Cassation, which holds that a criminal violation of medical secrecy has been committed as soon as the information has been divulged and regardless of the presence or absence of malicious intent. According to Dr. Duvoir the best procedure for a medicolegal expert to follow in general is this: The expert should advise the interested party to request of the injured person's physician a detailed certificate which the injured person could then submit to the expert. Dr. Daubrow objected that in the event of the patient's decease the claimants would have the status of third parties, and certificates delivered to third parties become *ipso facto* null and void. Under such circumstances an insurance company would be able to allege the incompetence of any certificate produced. Although a convinced upholder of professional secrecy, Dr. Daubrow could not help but admit that in certain cases the observance of secrecy may hamper the elucidation of the truth.

## Marriages

PAUL HARDIN HARMON to Miss Mary Logan Coleman, both of Springfield, Ill., September 13.

PAUL L. BERGSTROM, Kirkland, Ill., to Miss Lyne Gruhn of Columbus, Wis., September 4.

LIONEL GATES, Coalport, Pa., to Miss Mary H. Ryan of Mahanoy City, September 25.

HAROLD HENRI KLINGER, Akron, Ohio, to Miss Lucie Pickett of Fitzpatrick, Ala., recently.

MYRON REESE BAUMGARTNER to Miss Helen Berg, both of Dalton, Ohio, September 18.

WILLIAM T. DAILY, Brooklyn, to Miss Beatrix K. Robinson of New York, September 6.

HORACE F. BURTON, East Tawas, Mich., to Miss Helen Koth of Bay City, September 17.

ROBERT WILLIAM GRAVES to Miss Anne Yates, both of Durham, N. C., September 7.

REGINALD G. JOHNSTON to Mrs. Doris Greenwood, both of Medina, Ohio, recently.

## Deaths

**John Lawrence Yates** • Milwaukee; Johns Hopkins University School of Medicine, Baltimore, 1899; chairman of the Section on Surgery, General and Abdominal, American Medical Association, 1934-1935; assistant in pathology at his alma mater in 1901; assistant demonstrator of pathology at the University of Pennsylvania, Philadelphia, from 1902 to 1903; practiced in Milwaukee since 1906; member of the American Surgical Association, Society of Clinical Surgery and the American Association for Thoracic Surgery; fellow of the American College of Surgeons; served during the World War; consulting surgeon to the Milwaukee County and Milwaukee Children's hospitals, and attending surgeon to the Columbia Hospital; at one time on the staff of the Augustana Hospital, Chicago; aged 65; died, November 3, of a throat infection.

**Louis Marshall Warfield** • Milwaukee; Johns Hopkins University School of Medicine, Baltimore, 1901; member of the Association of American Physicians; fellow of the American College of Physicians; served during the World War; at one time associate professor of pathology, Milwaukee Medical College, professor of clinical medicine, Marquette University, instructor and lecturer on clinical chemistry and microscopy, Washington University Medical School, St. Louis, and professor of internal medicine at the University of Michigan Medical School, Ann Arbor; on the staffs of the Columbia, Evangelical Deaconess and Milwaukee County General hospitals; aged 62; was found dead in his automobile, September 28, of a bullet wound.

**John William Powers** • Milwaukee; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; clinical professor of orthopedic surgery, Marquette University School of Medicine; member of the Clinical Orthopedic Society and the American Academy of Orthopedic Surgeons; fellow of the American College of Surgeons; served during the World War; orthopedic surgeon to the Milwaukee County, St. Joseph's and Marquette University hospitals; aged 57; died, September 29, of arteriosclerosis.

**Adolf Gunderson** • La Crosse, Wis.; Koneglige Frederiks Universitet Medisinske Fakultet, Oslo, Norway, 1890; fellow of the American College of Surgeons; formerly member of the board of health; on the staffs of the La Crosse, Lutheran and St. Francis hospitals; at one time regent of the University of Wisconsin, Madison; aged 72; died, September 15, in Norway of bilateral nephrolithiasis, uremia and pyelonephritis.

**Harry Thomas Upshaw** • Pasadena, Calif.; St. Louis University School of Medicine, 1915; assistant clinical professor of surgery, University of Southern California School of Medicine, Los Angeles; fellow of the American College of Surgeons; on the staffs of the Huntington Memorial Hospital and the Los Angeles County Hospital; served during the World War; aged 46; died, August 12, of coronary thrombosis.

**Grafton Burke** • Fort Yukon, Alaska; University of the South Medical Department, Sewanee, Tenn., 1907; an Associate Fellow of the American Medical Association; fellow of the American College of Surgeons; for many years a medical missionary; medical director of the Hudson Stuck Hospital; aged 56; died, September 25, in the Virginia Mason Hospital, Seattle.

**Frank Wade Robertson**, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; member of the American Psychiatric Association; at one time medical superintendent of Stamford (Conn.) Hall; formerly senior physician and superintendent of the Elmira (N. Y.) Reformatory; aged 69; died, August 27.

**William Howard Halsey**, San Diego, Calif.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; for many years a surgeon in the U. S. Navy; served during the World War; formerly on the staff of St. Mary's Hospital, Milwaukee; aged 54; died, August 14, of coronary thrombosis.

**Frank W. Hendley**, Cincinnati; Medical College of Ohio, Cincinnati, 1885; veteran of the Spanish-American and World wars; formerly medical officer and member of the claims board of the U. S. Veterans Bureau; medical director of the Cincinnati Mutual Life Insurance Company; aged 78; died, September 12, in the Christ Hospital.

**Alfred Careno Croftan** • Chicago; Hahnemann Medical College and Hospital, Chicago, 1896; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; at one time on the staff of St. Mary of Nazareth Hospital; aged 67; died, August 22, in Pasadena, Calif., of carcinoma of the colon.

**Robert Hollingsworth Potts** • New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1918; assistant professor of medicine, Louisiana State University Medical Center; visiting physician to the Charity Hospital and on the staff of the Southern Baptist Hospital; aged 53; died, August 22.

**Argal Ernest Hubbard**, Oaklandon, Ind.; Chicago College of Medicine and Surgery, 1912; member of the Indiana State Medical Association; medical director and superintendent of the Sunnyside Sanatorium; formerly medical director of the Municipal Tuberculosis Sanitarium, Peoria, Ill.; aged 57; died, September 15.

**William Emmet Buehler** • Chicago; College of Medicine and Surgery, Chicago, 1904; Hering Medical College, Chicago, 1906; president emeritus and on the consulting staff of the Illinois Masonic Hospital; diagnostician on the staff of the American Hospital; aged 69; died, September 19, of coronary disease.

**William Townsend Dunning**, Gonzales, Texas; University of Texas School of Medicine, Galveston, 1909; member of the State Medical Association of Texas; served during the World War; formerly on the staff of the Holmes Hospital; aged 53; died, September 3, in the Nix Hospital, San Antonio.

**Pierson B. Peterson**, Honesdale, Pa.; Pulte Medical College, Cincinnati, 1891; member of the Medical Society of the State of Pennsylvania; formerly county coroner; at one time on the staff of the Wayne County Hospital; aged 74; died, August 8, of cerebral hemorrhage and arteriosclerosis.

**Mary Freyer Montgomery** • San Francisco; University of California Medical School, San Francisco, 1925; assistant clinical professor of surgery at her alma mater; assistant attending staff member, Children's Hospital; aged 39; died, August 30, in the University of California Hospital.

**Thomas Micajah Fly** • Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1903; formerly on the faculty of the University of Arkansas School of Medicine as associate in medicine; city health officer; aged 58; was found dead, September 21, of coronary occlusion.

**Leslie Ramsey Hazlett** • Butler, Pa.; Jefferson Medical College of Philadelphia, 1896; member of the American Academy of Ophthalmology and Oto-Laryngology; on the staff of the Butler County Memorial Hospital; aged 70; died, August 10, of coronary occlusion.

**Jonas Zettlemoyer**, Philadelphia; Temple University School of Medicine, Philadelphia, 1914; member of the Medical Society of the State of Pennsylvania; for many years connected with the bureau of public health; aged 75; died, August 9, in the Presbyterian Hospital.

**George F. Weber**, Ira, N. Y.; College of Physicians and Surgeons, Baltimore, 1889; at one time county coroner; for many years health officer; aged 74; died, August 30, in the Syracuse (N. Y.) Memorial Hospital of coronary thrombosis and diabetes mellitus.

**Otto Frederick Aufderheide**, St. Louis; Homeopathic Medical College of Missouri, St. Louis, 1900; member of the Missouri State Medical Association; aged 60; died, September 14, in the Christian Hospital, of intestinal obstruction due to intussusception.

**William Curtis Cross**, Ashtabula, Ohio; Cleveland University of Medicine and Surgery, 1896; veteran of the Spanish-American War; at one time member of the city board of education; aged 65; was killed, September 7, in an automobile accident.

**Frank Louis Waite** • Hartford, Conn.; Bellevue Hospital Medical College, New York, 1888; member of the American Ophthalmological Society; aged 72; on the staff of the Hartford Hospital, where he died, August 31, of cerebral thrombosis.

**Hugo Alexander**, Hoboken, N. J.; Columbia University College of Physicians and Surgeons, New York, 1911; member of the Medical Society of New Jersey; served during the World War; aged 51; died, September 14, of coronary embolism.

**Chester Arthur Miller**, Thedford, Neb.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1902; served during the World War; aged 64; died, August 29, in the Mercy Hospital, Council Bluffs, Iowa, of leukemia.

**Victor Bychower**, Malden, Mass.; Kaiser-Wilhelm-Universität Medizinische Fakultät, Strassburg, Germany, 1888; member of the Massachusetts Medical Society; aged 77; died in September at Bethlehem, N. H., of cerebral hemorrhage.

**Giles Edward Harris**, Hugo, Okla.; Louisville (Ky.) Medical College, 1905; member of the Oklahoma State Medical Association; served during the World War; aged 60; died in September of injuries received in an automobile accident.

**Luther Clarence Neill**, George Washington University School of Medicine, 1904; veteran of the Spanish-American War; aged 61; died, August 10, of rupture of aneurysm of the aorta and arteriosclerosis.

**Carl Schumann**, Delhi, N. Y.; New York Homeopathic Medical College and Hospital, 1887; member of the Medical Society of the State of New York; aged 75; died, August 2, in the Delhi Hospital of arteriosclerotic heart disease.

**Augustus Camillus Connor** Ⓢ Lexington, Texas; University of Louisiana Medical Department, New Orleans, 1883; past president of the Lee County Medical Society; aged 79; died, September 1, of hypostatic pneumonia.

**Charles Highsmith**, Dunn, N. C.; Baltimore Medical College, 1898; member of the Medical Society of the State of North Carolina; aged 66; died, September 9, in the Highsmith Hospital, Fayetteville, N. C., of pneumonia.

**Theodore Edward Schwarz**, Oakland, Calif.; Medical College of Ohio, Cincinnati, 1900, 1885; member of the California Medical Association; served during the World War; aged 60; died, August 4, of coronary thrombosis.

**Gustavus Crocker Simmons** Ⓢ Inverness, Calif.; Harvard University Medical School, Boston, 1885; at one time mayor of Sacramento and president of the board of health; aged 75; died, August 8, of coronary occlusion.

**Edward Everett Barbour**, Peoria, Ill.; Physio-Medical College of Indiana, Indianapolis, 1899; member of the Illinois State Medical Society; aged 69; died, September 22, of lobar pneumonia and Parkinson's disease.

**Rose D. Howe Jameson**, Bethlehem, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1891; member of the Connecticut State Medical Society; aged 73; died, August 17, of cerebral thrombosis.

**True Deloss Coe** Ⓢ Keithsburg, Ill.; Rush Medical College, Chicago, 1884; past president of the Mercer County Medical Society; aged 78; died, September 7, in a hospital at Monmouth of pneumonia.

**Kenneth Franklin Hughes**, St. Louis; University of Illinois College of Medicine, Chicago, 1937; aged 29; was killed, September 15, when the automobile in which he was driving was struck by a train.

**John G. W. Knoll**, Buffalo; University of Pennsylvania Department of Medicine, Philadelphia, 1888; for many years on the staff of the Deaconess Hospital; aged 73; died, August 26, of food poisoning.

**Anthony Caputi**, Brooklyn; Hahnemann Medical College and Hospital of Philadelphia, 1935; aged 30; on the staff of the Prospect Heights Hospital, where he died, September 5, of pneumonia.

**Edward Freeman Walsh**, Pasadena, Calif.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1886; aged 80; died, August 31, of diabetes mellitus.

**Alberto Garcia de Quevedo**, Washington, D. C.; University of Maryland School of Medicine, Baltimore, 1915; aged 45; died, August 29, of cirrhosis of the liver and diabetes mellitus.

**James Ignatius Keaney Jr.**; St. Joseph, Mo.; St. Louis University School of Medicine, 1906; on the staff of the State Hospital Number 2; aged 62; died, September 9, of cardiac disease.

**Harry Samuel Hughes** Ⓢ St. Louis; St. Louis University School of Medicine, 1905; aged 56; was killed, September 15, when the automobile in which he was driving was struck by a train.

**William F. Berkenstock**, Philadelphia; Hahnemann Medical College of Philadelphia, 1884; aged 76; died, September 5, in Atlantic City, N. J., of arteriosclerosis and aortic stenosis.

**William Frederick Imrie Dey**, New York; University of Toronto Faculty of Medicine, 1910; served during the World War; aged 56; died, September 16, of heart disease.

**Clarence S. Branson** Ⓢ St. Joseph, Mo.; Ensworth Medical College, St. Joseph, 1910; on the staff of St. Joseph's Hospital; aged 50; died, September 16, of coronary thrombosis.

**William Herbert Nute** Ⓢ Exeter, N. H.; Medical School of Maine, Portland, 1881; on the staff of the Exeter Hospital; aged 80; died, August 18, of coronary thrombosis.

**Thomas Bassett Keyes** Ⓢ Lake Bluff, Ill.; Albany (N. Y.) Medical College, 1895; aged 62; died, October 2, of myocarditis.

**Andrew Foster Whitford**, Cambridge, Mass.; Baltimore University School of Medicine, 1893; died, August 24.

## Correspondence

### MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION

*To the Editor:*—I have just read the interesting editorial on page 1770 of THE JOURNAL of November 5 and also the news item on page 1775 with regard to the action of the American Public Health Association at its sixty-eighth annual meeting at Kansas City, Mo., October 25-28. Every one in attendance at the meeting was very much distressed at the total misconception of the attitude and action of the association by the public press, but we are much more disturbed because of the failure by THE JOURNAL to understand this action. The resolutions speak for themselves. The following resolution was written by Dr. Abel Wolman, the distinguished sanitary engineer of Baltimore, who is president of the association, and was unanimously adopted on motion of Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service:

The American Public Health Association records its appreciation of the participation in its deliberations during this annual meeting week of Dr. Irvin Abell, President of the American Medical Association. It records with pleasure its agreement with the approval in principle, at a recent special session of the House of Delegates of the American Medical Association, of the content of the National Health program presented by the Interdepartmental Committee to the National Health Conference. The association pledges its continued cooperation and support to the American Medical Association in the translation of this policy into action.

There was no difference of opinion expressed in the Governing Council, which corresponds with the House of Delegates of the American Medical Association; the resolution with regard to the Report of the Technical Committee on Medical Care as published in THE JOURNAL expressed exactly the unanimous feeling of the Governing Council. There was not a single expression made in favor of so-called health insurance and there was no difference of opinion between the medical and lay members of the association. The action was unanimous, the consideration was as constructive and on as high a plane as that of the memorable special session of the American Medical Association in Chicago, and the practical agreement between the American Medical Association and the American Public Health Association should be emphasized, rather than the studied effort to create the impression that there was a division of opinion.

I am sorry that you and every other thoughtful member of the medical profession could not have been present at this meeting, where those who specialized in public health found themselves in practically complete accord with the splendid statement made by Dr. Irvin Abell as President of the American Medical Association.

Following the adoption of the resolution, and the precedent set by the American Medical Association, the following committee was appointed to confer with the Interdepartmental Committee, the American Medical Association, the American Dental Association, the National Organization of Public Health Nurses, the Conference of State and Territorial Health Officers and other agencies: Drs. Abel Wolman, president of the association, as chairman; J. N. Baker of Alabama; Louis I. Dublin, vice president of the Metropolitan Life Insurance Company of New York; Harry S. Mustard of New York; John L. Rice of New York; Felix J. Underwood of Mississippi, and myself. Drs. E. S. Godfrey, president-elect, and Reginald M. Atwater, executive secretary of the association, are ex officio members.

As you know, Dr. Baker, Dr. Underwood and I are members of the House of Delegates of the American Medical Association. The chairman of the Committee on Resolutions was Dr. A. J. Chesley of Minnesota, who is secretary of the Conference of State and Territorial Health Officers and a member of the Committee on Study of Medical Care of the American Medical Association.

I desire respectfully to submit that those of us interested in the preservation of the integrity and traditions of American

medicine can serve it and the American people better by emphasizing the essential unity of all branches of the medical and allied professions in support of the constructive sections of the National Health Program, and in the practically unanimous objection to compulsory health insurance, than by reemphasizing the captious objections raised by individuals in the various organizations.

A. T. McCORMACK, M.D., Louisville, Ky.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### DIVERTICULITIS

*To the Editor:*—A patient aged 55 has had vague abdominal pains for nearly a year. Most of the pain seems to be in the left lower quadrant. Complete examination is quite normal except for a blood pressure of 166 systolic, 104 diastolic and extreme nervousness. X-ray examination of the stomach, gallbladder and lungs is normal; the electrocardiogram is normal. A barium sulfate enema reveals diverticula in the sigmoid with rather marked spasm at the junction of the descending and sigmoid colon. I have tried many diets and various medications, such as atropine, phenobarbital and bromides. The bowels are not constipated. I would appreciate anything further you may suggest.

M.D., Ohio.

**ANSWER.**—The abdominal distress is undoubtedly due to the diverticula and associated local spasm. Because of the patient's hyperkinetic state he is more susceptible to pain stimuli. The treatment should consist of a nonresidue diet and an oil retention enema each night of 3 or 4 ounces (about 100 cc.) of olive oil, to which 20 grains (1.3 Gm.) of thymol iodide powder should be added. Antispasmodics should be tried such as novatropine. If these measures fail, an attempt may be made to fill the diverticula with a nontoxic substance. This can be accomplished by giving barium sulfate or bismuth subcarbonate in 2 ounce (60 Gm.) doses once a week for six weeks.

### SKIN GRAFT TO FINGER TIP

*To the Editor:*—When a patient accidentally cuts off the end of the finger tips for from one-fourth to one-half inch, leaving the bone exposed, would it be feasible to use a plaster cast immobilizing the hand and arm to the opposite side of the patient's abdomen and making a graft of the skin from that area to cover the stumps? Will such skin later provide a serviceable practical skin that will stand up satisfactorily under hard physical usage?

M.D., California.

**ANSWER.**—The immediate covering of such losses, where the wound has been from a clean cut rather than a crushing one, is desirable and the skin of the flank is acceptable. Occasionally, by simply flexing the finger on the hand, a small flap from the hand can be put in place. Still more infrequently it may be possible, if there has been a clean excision of the tip of a finger, to do a free graft provided the tip itself has not been too greatly contaminated. The transplanted skin from any area will not have the characteristic tough padding of the finger tip and may need the protection of a glove if exceptionally hard work is to be done.

### ARTHRANOL, ERTRON AND LYXANTHINE-ASTIER

*To the Editor:*—What information can you give me concerning the following in the treatment of arthritis? (1) Arthranol (*Time*, Sept. 26, 1938); (2) Ertron (Nutrition Research Laboratories, Inc., Chicago); (3) Lyxanthine-Astier (Gallia Laboratories, Inc., New York).

M.D., Brockport, N. Y.

**ANSWER.**—1. Arthranol, stated to be a mixture containing essentially ammonium phosphate, ammonium iodide, ammonium chloride, ammonium benzoate, ammonium salicylate and water, was discussed editorially in *THE JOURNAL* October 8, page 1381. It is recommended for use in the treatment of arthritis, but no competent evidence is available to indicate its usefulness.

2. Ertron was the subject of an adverse report of the Council on Pharmacy and Chemistry (*THE JOURNAL*, July 10, 1937, pp. 132 and 133). It is claimed to be a highly potent vitamin D preparation. The Council found no evidence to establish the value of such preparations in the treatment of arthritis.

3. Lyxanthine-Astier has not been examined by the Council nor has the American distributor, Gallia Laboratories, Inc.,

requested the Council to consider the preparation for the purpose of determining its eligibility for inclusion in New and Nonofficial Remedies.

According to advertising material distributed by the Gallia laboratories in 1936, Lyxanthine-Astier is a "new product developed by the famous research laboratories of Dr. P. Astier of Paris, France," an "efficient anti-arthritis, antirheumatic" associating "sulphur, calcium and iodine with the potent uric acid solvent, lysidin bitartrate." The following formula appears in the advertising: "Iodo-propanol-sulphonate of sodium 12 grs., bitartrate of lysidin 9 grs., calcium gluconate 12 grs., sodium bicarbonate 37 grs., tartaric acid 15 grs., citric acid 6 grs., powdered sugar 9 grs., oil of lemon, several drops."

Although lysidin is claimed to be the "main active element" of Lyxanthine, in his studies carried out some twenty years ago, Hanzlik reached the conclusion that there is sufficient scientific evidence to indicate the worthlessness of lysidin as a urate solvent (*J. Lab. & Clin. Med.*, February 1917; Report of the Therapeutic Research Committee, 1917). The other active "anti-rheumatic agents" of Lyxanthine are stated to be iodine and sulfur in the form of iodo-propanol sodium sulfonate and calcium gluconate. The latter substance has been accepted by the Council for inclusion in New and Nonofficial Remedies as the effective agent for obtaining the therapeutic effects of calcium. However, the Council's publication gives no recognition to claims of usefulness as a treatment for arthritis.

Lyxanthine-Astier appears to be a needlessly complex and unscientific mixture of well known substances marketed under a fanciful name with claims that have not been confirmed by competent investigations.

### BILATERAL PHRENICECTOMY FOR TUBERCULOSIS

*To the Editor:*—Is bilateral permanent phrenicectomy compatible with life where the operations on the two sides are done at long intervals on persons who have adequate functional lung tissue in the upper portions?

M.D., California.

**ANSWER.**—Not only is bilateral phrenicectomy compatible with life but even simultaneous bilateral phrenic exeresis may be performed without causing visible harm. In dogs, unilateral multiple intercostal nerve paralysis has been performed, in addition, without causing death. W. S. Lemon (*Am. J. M. Sc.* 177:319 [March] 1929) reported one dog on which he did complete bilateral, intercostal neurectomy and bilateral phrenic paralysis in four stages without death, and without dyspnea except under anesthesia. The advisability of such operations is another matter. Alexander (Collapse Theory of Pulmonary Tuberculosis, 1937, p. 152) says that he has never seen a patient for whom a permanent bilateral phrenic paralysis was indicated. Even temporary bilateral paralysis is rarely performed. Alternating temporary paralysis, however, is not infrequently resorted to, time being allowed for function to return to the side operated on first.

### HEMOPHILIA

*To the Editor:*—A boy aged 16 is a real hemophiliac. Recently I read in the *Lancet* (2:1142-1149 [Nov. 14] 1936, about a supposed aid in hemophilia. The article spoke of mixing egg white with potassium bromide and keeping this mixture in an incubator at body temperature for several days. Then this mixture was injected for treatment of the blood condition. Is there any scientific basis for this mixture doing any good?

J. H. BURROWS, M.D., Williamsport, Pa.

**ANSWER.**—Recent research in hemophilia has been directed toward a study of the blood serum. The investigations of Patek and Taylor (*J. Clin. Investigation* 16:133 [Jan.] 1937) and of Pohle and Taylor (*ibid.* 16:741 [Sept.] 1937) have suggested that in hemophilia there may be a deficiency in certain serum globulins. They have shown that a globulin substance prepared from normal human serum accelerates clot formation of hemophilic and normal blood but that hemophilic blood serum lacked this property. A similar theory is suggested by the studies of Eley, Green and McKhann (*J. Pediat.* 8:135 [Feb.] 1936) and of Bendien and Grevel (*Acta. brev. Neerland.* 5:135, 1936) on the effects in hemophilic patients of human placental extract, which may contain a similar globulin substance.

There may be some relation between these studies and those of Timperley, Naish and Clark referred to in the question. These authors report that repeated injection of an extract prepared from egg white reduces the clotting time and controls hemorrhage in hemophilic patients. The apparently favorable results reported by them have not as yet been corroborated by others. No further reports on the use of this preparation have appeared in the American or European literature. As the authors themselves state, more study and prolonged testing is necessary before an evaluation of the effect of this substance can be made.

## TREATMENT OF SYPHILIS

To the Editor:—A woman aged 27, separated from her husband, came to me June 6, 1936, for a check up at the insistence of a partner who had contracted a virulent case of gonorrhea. She stated that she had never had a venereal infection or any symptoms relative to the genital tract and he emphatically denied any other source of contact. Another physician had previously taken urethral, vaginal and cervical smears and had found them negative. I repeated the smears and also took blood for a Hinton and a complement fixation test. The smears came back negative but the blood reports were positive for both syphilis and gonorrhea. I repeated the test and got the same results. Since then the woman has been under my care and has had the following medication with the following results: one course of nearsphenamine totaling thirteen injections or 5.95 Gm. The Hinton test after the seventh injection gave positive results. One course of twelve thiobismol injections totaling 34.4 Gm. The Hinton test after the eighth injection was positive and the spinal fluid reading of the colloidal gold test was 00+1100000. The Wassermann reaction of the spinal fluid was negative. Because of reactions with nearsphenamine I tried starting the second course of arsenicals with mapharsen and gave two injections of 0.04 Gm. each. On the third injection I reverted to nearsphenamine, giving 0.3 Gm. Twelve more injections of sulfarsphenamine were then given, totaling 3.9 Gm. The substitution was made because of difficulty with small veins. The Hinton reaction after the sixth and fifteenth treatments was still positive. After the fifteenth treatment the complement fixation test was positive. The spinal fluid examination gave a negative Wassermann reaction and colloidal gold ++++000. The second bismuth course consisted of five injections of thiobismol (15 grains) and five injections of bismuth subsalicylate in oil (14 grains). There have been seven injections of sulfarsphenamine in the third course, totaling 2.1 Gm. The Hinton reaction following the last injection was still positive. To date the patient has had nearsphenamine 6.25 Gm., sulfarsphenamine 6 Gm., mapharsen 0.08 Gm., thiobismol 49.4 grains, bismuth subsalicylate 14 grains. In conjunction she has also had two courses of yellow mercurous iodide one-eighth grain (0.008 Gm.) three times a day for one month each. She has been lax in receiving treatment and should have had nearly double this amount had she been regular. In addition she married again one year ago without permission and has since had two miscarriages at the third month. I had planned to give eight more injections of sulfarsphenamine and ten more of bismuth subsalicylate in oil before allowing a period of probation. What chance is there to develop central nervous system syphilis and what should be done to prevent it as much as possible? Is there any likelihood of infecting her husband? Will it be possible to reverse the Hinton reaction at this late date and what should be done to favor it? Would tryparsamide be indicated? Will it be possible for her to carry to term successfully?

M.D., Massachusetts.

ANSWER.—This patient has received fourteen injections of nearsphenamine totaling 6.25 Gm., nineteen injections of sulfarsphenamine totaling 6 Gm., two injections of mapharsen totaling 80 mg., seventeen injections of thiobismol totaling 1.27 Gm. of metallic bismuth, and five injections of bismuth subsalicylate totaling 0.325 Gm. of metallic bismuth.

Some of the other data that are most necessary, however, are not furnished. No mention is made of physical examination—simply laboratory data are furnished. No mention is made of anything in the spinal fluid but the colloidal gold test and the Wassermann reaction. In an early lumbar puncture the cell count is most valuable. Moreover, it is not stated how often thiobismol injections were given. This may be one of the reasons why the patient has not responded better to therapy, though it is true that she apparently has been negligent. Studies by Sollmann, Cole and Henderson (*Ann. J. Syph.*, 21:480 [Sept.] 1937) have shown that thiobismol must be administered three times a week to achieve a therapeutic lasting level of bismuth in the blood stream. If the injections are given but once a week there is little or no effect on the syphilis, for the peak level of bismuth in the blood stream after a single injection is reached and is over in twenty-four hours, and thereafter there is only a small level, which continues for a few days. On that account, if one uses thiobismol the injections must be given three times a week.

It would be well to go over the patient carefully, looking particularly for evidence of cardiovascular syphilis and for central nervous system involvement. Moreover, a lumbar puncture should be done at once, a cell count, a colloidal gold test, a Pandy test, and a Wassermann test on the fluid in amounts of 0.1 cc. up to 1 cc.

It is possible that the patient has had her syphilis for some time, and if this is true there would not be so much danger of her husband's being infected. He should be examined, however, and a Wassermann test taken.

If the lumbar puncture is done now and is negative, and the physical examination shows no evidence of central nervous system involvement, the chances are that the patient will not develop central nervous system involvement after this period of time. The Cooperative Clinical Group studies have shown that practically all involvement of the central nervous system actually occurs early in the infection although symptoms may not appear for years. Tryparsamide would not be indicated unless there is involvement of the central nervous system.

If physical examination is negative and if the lumbar puncture is entirely negative, this patient should receive alternating courses in a continuous manner of ten injections each of nearsphenamine or mapharsen and of bismuth subsalicylate for a further period of one year and in the succeeding year two courses of injections of bismuth subsalicylate with a rest period between the courses. The Cooperative Clinical Group has already recommended that every syphilitic woman who is pregnant should be treated for syphilis throughout the pregnancy. This gives the best promise of a living, healthy child.

## TULAREMIA

To the Editor:—A patient died from an infection at first presumed to have been caused by cigaret ashes which flew into his right eye. He rubbed the eye and it was red and irritated and later became infected. At first it was diagnosed as streptococcal infection but it did not respond to treatment. Blood tests were made, the first two being negative for tularemia. It had been suggested that there was a tularemic ulcer under the upper lid of the right eye. Further tests showed tularemia and treatment was given but the patient developed pneumonia and died. Autopsy disclosed the tularemia germ. As I understand it there are only about fifty cases reported of the ocular glandular type of tularemia. Could it be possible for this patient to have been bitten by a tick and for the poison to have gone through his system and settled in his eye? Is it possible for the tularemia germ to enter through the pores of the skin without the avenue of an abrasion or opening to the blood stream? A theory has been advanced that he might have smashed a tick with his fingers, wiped it on his trousers or clothes and later came in contact with it by his hands and rubbed it into his eye. The man was a fastidious individual, meticulous in his habits, and immediately preceding the episode when he got the ashes in his eye he had bathed thoroughly and had not handled any rabbits or been in contact with any. He had been out to a dude ranch the day this happened but stated that he was not bitten by a tick. Nor was he where he would come in contact with ticks other than being in the early morning outside the main ranch building with a lariat that belonged to him, throwing it to lasso a post. But after that he swam in the pool and bathed several times. His first complaint of his eye was when he and a young woman were riding home, both smoking cigaretts, and a gust of wind blew the ashes into the eyes of both. The woman was not affected at all, but the patient rubbed his eye rather violently and later stopped and bathed it with water.

ROBERT R. HARROLD, North Hollywood, Calif.

ANSWER.—The presence of an ulcer from tularemia under the upper eyelid of the right eye leaves little doubt that this ulcer was the primary lesion and that the invasion of other tissues was secondary to the eye infection.

There seems to be unmistakable evidence that the causative organism of tularemia may invade unbroken skin or mucous membrane. In glandular tularemia there is no demonstrable primary ulcer. It is possible to infect guinea pigs and rabbits by dropping a suspension of infected tissue of the spleen onto the skin or into the conjunctival sac.

The development of oculoglandular tularemia usually results from inadvertently wiping the eye with fingers that have been contaminated by handling infected animals or by crushing an infected wood tick or deer fly.

## ALOPECIA FROM LUPUS ERYTHEMATOSUS

To the Editor:—Since the age of 6 an unmarried woman aged 21 has had alopecia in the frontal and occipital regions of the scalp as a consequence of a probable lupus erythematosus. The few scattered hairs in the scarred regions are fine and short; the marginal hairs are longer and thicker. Hence she has had to wear a wig. What procedure besides scalp grafting is possible? Can individual hairs be sewed into the scalp? What is the relative efficacy of the different methods? Any treatment even of doubtful merit will be carefully considered. M.D., New York.

ANSWER.—Unfortunately lupus erythematosus when it affects the scalp produces areas of alopecia and atrophy. The only recourse this patient can have is wearing a wig. Grafting hair on the scalp and sewing hairs into the scalp are impossible procedures.

## SYMPATHECTOMY FOR SPASTIC PARALYSIS

To the Editor:—I would appreciate information as to the merit of sympathectomy for an after-birth hemiplegic spastic paralysis due to cerebral hemorrhage.

M.D., New York.

ANSWER.—The enthusiasm created by the work of Hunter and Royle during their visit to the United States in 1924, when they proposed the operation of sympathectomy for the purpose of relieving spasticity in cerebrospastic paralysis, has long since subsided. Patients who appeared to be benefited shortly after operation were found within a short time to be as spastic as they had been previous to the operation. From the standpoint of clinical experience in the use of this operative procedure, it is doubtful whether there is any permanent benefit to be derived from it.

## POWDERS FOR ALCOHOLISM

To the Editor:—1. There has come to my attention recently a powder which is used to place in alcoholic beverages and causes immediate sickness; it is said to terminate the effects of overindulgence of alcohol immediately. This I cannot believe. The names of the two powders mentioned are "Micky Finn" and "Mrs. Moffat's Shoo Fly Powder." Can you give me some information on this subject? 2. Is there any powder which can be added to an alcoholic beverage that cannot be detected by taste and will cause a distaste to alcohol? M.D., Massachusetts.

ANSWER.—1. The report on the Mickey Finn Powders was sent to the American Medical Association Chemical Laboratory Nov. 22, 1918, by Dr. William D. McNally, then coroner's chemist for Cook County. The product was labeled "Mickey Finn Powders—Great Antidote for the Liquor Habit." The powder weighed from 9.57 to 13.56 grains and contained 98.19 per cent tartar emetic. Similar analysis of "Mrs. Moffat's Shoo Fly Powders" showed that each powder weighed from 2.88 to 2.97 grains. An analysis showed 98.6 per cent tartar emetic.

2. No.

## POSSIBLE GLOMUS TUMOR

To the Editor:—A patient has numerous subcutaneous nodules, some about the size of a pea, some about half that size. They are painful. One of them has been removed and examined by a competent pathologist, who diagnosed it as angiofibroma. He had no treatment to offer. The patient is suffering severely and so far the only thing that I have found to give her relief has been salicylates. However, she is having as much trouble now as she had eight months ago, and I wonder whether there is any therapy that will cure this condition.

A. C. FORTNEY, M.D., Fargo, N. D.

ANSWER.—From the meager description of a painful tumor of the skin, the deduction is that this patient most probably has a glomus tumor. One might suggest a recheck of the case and comparison of the pathologic slide with the published accounts of the microscopic appearance and the clinical picture of glomus tumor. (Andrews, G. C.: Textbook of Dermatology, ed. 2, Philadelphia, W. B. Saunders Company, 1938, p. 705). Treatment consists of removing each nodule surgically. Electro-surgery also may be used.

## COMPRESSES IN CELLULITIS

To the Editor:—THE JOURNAL, September 3, page 960, carries an answer to the question What is the rationale of cold compresses of magnesium sulfate in cellulitis? I would like to call your attention to the answer, which states that "hot wet dressings produce an edema of the underlying tissue and capillary changes in the vessels with a varying amount of cellular infiltration." This answer is at variance with factual information in the field of capillary physiology. Local edema due to a cellulitis does not develop if circulation is maintained. Moist heat induces local circulatory acceleration. During work muscles take up from ten to twenty times more oxygen than when at rest. Heat, within certain limits, influences oxygen diffusion about 1 per cent per degree. This indicates increased capillary circulation in order to supply the oxygen. If the circulation was not accelerated by moist heat and by functional activity, the rapid exhaustion of oxygen from the blood would result in a cyanotic color which is characteristic of poor circulation. One does not see cyanosis from the use of moist heat compresses. Carbonic acid is inseparably bound up with increased functional activity. Pure carbon dioxide will produce dilatation of arteries and capillaries and a rapid current of blood. There is no reason for believing that the accelerated circulation induced by moist heat can be produced independently of the formation of carbon dioxide. Clinically, the picture induced by muscular activity and the picture induced by moist heat are similar. Krogh (The Anatomy and Physiology of Capillaries, New Haven, Conn. Yale University Press, 1929) found when working with rabbits that if the animals were kept warm the arteries and arterioles were dilated; the capillaries were not greatly involved in the dilatation but the venules and veins were somewhat dilated by the increased flow. In the skin of man, moderate moist heat does not induce the contracted, elevated papillae of refrigeration. It must be remembered that there are no capillaries in the skin of man outside those in the papillae. In a study of capillary loops around the finger tips of man, Krogh noted that warmth allowed two corpuscles to pass the field of vision when normally only one had been noted. Under the influence of cold, agglutination of corpuscles was noted and the flow appeared retarded. Clinically, if vessels are not damaged and the circulation has not failed completely, local edema disappears under moist heat compresses. Naturally there is a limit to physiologic reactions. If capillary function has failed completely, surgery is indicated, not therapy. "Changes" in capillary walls and cellular infiltration are not the result of application of compresses of moist heat. If uncontrolled dry heat or refrigeration is used, "changes" may be expected. A better understanding of the physiology of capillary function should result in the abandonment of cold packs as a means of combating a localized suppurative cellulitis. Dental and mastoid suppurations are commonly refrigerated. The abdomen is commonly refrigerated with ice packs. Enough evidence is available today to indicate that refrigeration of a local cellulitis is empiricism.

JOSEF NOVITZKY, D.D.S., San Francisco.

## Medical Examinations and Licensure

## COMING EXAMINATIONS

## STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, November 12, page 1871.

## NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, Feb. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

## SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. Written examination, Part I, will be held in various cities of the United States and Canada, April 8. Oral examinations for all candidates, St. Louis, May 13-14. Applications must be filed not later than sixty days prior to the date of the examinations. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF INTERNAL MEDICINE: Written examinations will be held in various parts of the United States, Feb. 20. Application must be received on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada, Feb. 4. General oral, clinical and pathological examinations for all candidates (Groups A and B) will be given in St. Louis, May 15-16. Applications must be filed not later than sixty days prior to the date of examination. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: St. Louis, May 15. Applications must be filed before February 15. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis.

AMERICAN BOARD OF ORTHOPEDIC SURGERY: Memphis, Tenn., Jan. 13-14. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: St. Louis, May 12-13. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: New York, April 26. Appointments must be made before Dec. 26. St. Louis, May 16. Appointments must be made before Jan. 16. Cincinnati, Nov. 14-15. Appointments must be made before July 14. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 28-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: St. Louis, May 11-14. Sec., Dr. Byrl R. Kirklind, 102-110 Second Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY: New York, Jan. 13-15. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

## Missouri June Report

Dr. Harry F. Parker, secretary, State Board of Health of Missouri, reports the written examination held at St. Louis, June 2-4, 1938. The examination covered fifteen subjects. An average of 75 per cent was required to pass. One hundred and sixty-five candidates were examined, 162 of whom passed and three failed. Fifteen physicians were licensed by reciprocity and five physicians were licensed by endorsement July 26. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
State University of Iowa College of Medicine.....	(1937)		79.5

## Book Notices

**The Biology of Arteriosclerosis.** By M. C. Winternitz, M.D., R. M. Thomas, M.D., and P. M. LeCompte, M.D., the Department of Pathology, Yale University School of Medicine, New Haven, Connecticut. Cloth. Price, \$4. Pp. 142, with 116 illustrations including 56 colored illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1938.

This work, sumptuously illustrated in color and black and white, is a study of the results obtained by injecting suspensions of Higgins' engrossing ink into arteries and solutions of Berlin blue into veins. The only variation from standard injection methods was the use of high pressures: from 800 to 1,000 mm. of mercury in the injection of coronary arteries up to 1,500 mm. of mercury in the injection of leg vessels. After injection, the tissues were cleared by the method of Spalteholz. The illustrations are for the most part drawings, with photomicrographs, some by the Kodachrome method, and photographs. There are many picturesque drawings of the various capillary and sinusoidal systems found. The authors were influenced by a hope that they could demonstrate intimal vessels in normal arteries, which previous workers had failed to do. Their work furnishes added evidence, if any were needed, that the intima of normal arteries is not vascularized, since all the illustrations of injected human arteries showing intimal vessels are the seat of advanced atherosclerosis.

Much stress is laid on the finding of hemorrhages in some atherosclerotic lesions. It is difficult to follow the reasoning of the authors that these hemorrhages may have an etiologic relation to the disease atherosclerosis. The hemorrhages arise from vessels of capillary systems that are produced to supply nutrition to atherosclerotic lesions, as these enlarge beyond the possibilities of support by diffusion through the intima. In other words, the lesions in which capillary systems are found are already advanced lesions. How hemorrhages into advanced lesions can be etiologic factors in atherosclerosis is not explained.

The possibility that infection may be the etiologic factor in atherosclerosis is again presented, despite the contrary opinion of authorities, almost without exception, who have studied this disease. The authors refer to two early papers from the University of Oregon supporting this thesis but do not refer to a later paper from the same laboratory (Menne, F. R.; Beeman, J. A. P., and Labby, D. H.: Cholesterol-Induced Arteriosclerosis in Rabbits, with Variations Due to Altered Status of Thyroid, *Arch. Path.* 24:612 [Nov.] 1937) in which it is concluded: "In our considerations it seems evident that many agencies of disease, the variations in diet, the disturbance of internal secretions, infections, the traumatism of certain occupations and the influence of posture all aid in the development of arteriosclerosis only as they modify these two basic factors of hypercholesteremia and mechanical strain."

The bibliography on nutrition of the blood vessel wall by Dr. Elizabeth M. Ramsey, which is republished (*Yale J. Biol. & Med.* 9:13 [Oct.] 1936) as an appendix, is thorough. On the other hand the bibliography on arteriosclerosis lacks reference to many modern papers.

The book has value only as a study of the vascularization of advanced atherosclerotic lesions. Inferences are drawn that are not justified by the material presented and that tend to confuse the issue with respect to etiology.

The publisher is to be complimented on the makeup of the book, the reproductions and the clear type. The drawings are excellent.

**Les réactions d'équilibre chez l'homme: Étude physiologique et clinique des réactions d'équilibre sur la table basculante.** Par Jules Zador. Préface de M. André-Thomas. Paper. Price, 80 francs. Pp. 255, with 214 illustrations. Paris: Masson & Cie, 1938.

In this monograph Zador has attempted to extend to the clinic the experimental studies of Rademaker on equilibration, as Rademaker and Garcin had done previously. In his study he used a horizontal table on which the subject was placed in various positions, supine, prone, on the hands and knees or the elbows and knees, sitting and standing. The table was so constructed that it could be suddenly tilted, at first in only two directions about a single horizontal axis, but in a later model in four directions. The author accepts and bases his work on Rademaker's conclusions that the reactions which occur following sudden tipping of the table are labyrinthine in origin and following slow tipping are proprioceptive in origin. He is concerned only with the former and further quotes Rademaker to the effect that the reaction following sudden tipping is divisible into three phases: the labyrinthine, the passive, imposed by gravity on the body, and the proprioceptive.

He reports his observations on the normal adult in which the reaction can be simply stated as a tendency for the body to attempt to maintain the position present before the table tipped. In the infant he finds that by the age of 8 months the child attempts to maintain his position on the table but that the reaction until the age of 6 years is different and after that age is comparable to the normal adult reaction. He then records his results in a variety of pathologic conditions, disturbances of the vestibular nerves, cerebellar disease, cerebellovestibular syndrome, tabes dorsalis, hemiplegia without "static ataxia," extrapyramidal hyperkinesia, parkinsonism, catatonic stupor of dementia praecox and idiocy. In this section the book is most unsatisfactory. The clinical information is brief and often absent, and anatomic confirmation of the clinical diagnoses is wholly lacking. The reader is forced to accept the author's or his colleagues' interpretation of the cases. Such, of course, is very inconclusive and unsatisfactory in a monograph which poses as the presentation of a piece of human neurophysiologic investigation and presumes to offer a new technic for the examination and diagnosis of cases of nervous disease.

The author states that with bilateral involvement of the vestibular nerve the normal reactions are lost. They may be lost with a unilateral lesion, but compensation tends to occur and after a time the normal response may return. With chronic cerebellar disease the normal reactions are retained. Experience with acute cerebellar lesions is too limited to justify any statement and the method is not applicable to cases of tumor. With tabes dorsalis and catatonia the reactions are normal. With "extrapyramidal hyperkinesia" and in idiots the reactions revert to the infantile type. There is no index.

**The Essentials of Human Embryology.** By Gideon S. Dodds, Ph.D., Professor of Histology and Embryology, School of Medicine, West Virginia University, Morgantown, West Virginia. Second edition. Cloth. Price, \$4. Pp. 316, with 182 illustrations. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Limited, 1938.

This is a clear and simple presentation for the use of medical students of the facts and point of view which are essential for any understanding of human anatomy. It is prefaced by an excellent discussion of the physiology of reproduction in mammals as it is understood at the present moment. The theorizing and comparisons so dear to the heart of the embryologist are reduced to a minimum. This goes too far sometimes. The human yolk sac, for example, is dismissed as a "relic." At the eight weeks stage, to be sure, it seems to be nothing more than a useless vestige, but when one considers that during the third and fourth weeks the embryo takes form as it is spread out on the surface of the yolk sac precisely as in reptiles and birds, it is obvious that the yolk sac could not have dropped out of the life history of man without fundamentally modifying the whole scheme of development. Mention is made later of it as a hematopoietic organ; up to the fifth week it is the hematopoietic organ *par excellence*. Similarly, the pronephros and mesonephros have persisted through the ages because they are essential not only for the development of the wolffian duct but for

maintaining the patency of the duct and later the urogenital sinus (Boyden). The illustrations are done in the British manner—simple line drawings free from all ambiguity. Few create false impressions. The wofully incorrect figure of the "Bulle" embryo is here as in so many other textbooks. Figure 12 gives an erroneous idea of the character and mode of spread of the implantation syncytium. The chapter on the nervous system is written from the point of view of the neurologist, which is quite unusual in works on embryology. Books of this sort are good if the instructor points out that human embryology is not as fully worked out as the text seems to indicate. He does point out that the mechanism of development is still largely a mystery, but it would have been possible to say that recent experimental studies have revealed at least some of the factors concerned in normal development.

**Life, Heat, and Altitude: Physiological Effects of Hot Climates and Great Heights.** By David Bruce Dill, Fatigue Laboratory, Harvard University. Cloth. Price, \$2.50. Pp. 211, with 25 illustrations. Cambridge: Harvard University Press; London: Oxford University Press, 1938.

There seems no great justification for the publication of this volume. From a medical or scientific standpoint, Dill's material on the physiologic effects of high temperatures and high altitudes has already been well presented in readily available journals and its points of practical importance have been widely appreciated. Insufficient linkage exists between heat and the effects of altitude to justify his attempt at unified presentation. The chapter on desert animal life is interesting. The first sections on heat deal almost exclusively with effects on the water and salt balance and on the circulatory system, neglecting entirely the changes in internal combustion and in adrenal function that are brought about by adaptation to difficulty of heat loss. Desert animal life the author oversimplifies by division into those forms which obtain their water supply from plants and those which take it as free water. Surely there are all degrees of intervening gradation, just as exist in nondesert regions. And in his final sections on altitude effects no attention is devoted to barometric pressure as such, all observations centering around the results of oxygen deprivation. The presentation presumes to be physiologic in character, but only in the technical parts dealing with water and salt balance at high temperature and with the effects of low oxygen tensions is the material adequately handled. The medical reader will find in the book little of value that has not already been well stressed in scientific and medical journals, while for the layman the technical material and presentation make reading difficult and uninteresting.

**The Occupational Treatment of Mental Illness.** By John Ivison Russell, M.B., Ch.B., F.R.F.P.S., Medical Superintendent, North Riding Mental Hospital, Yorkshire, England. With foreword by William Rees-Thomas, M.D., B.S., F.R.C.P., Senior Medical Commissioner, Board of Control. Cloth. Price, \$2.50. Pp. 231, with 41 illustrations by Joseph Blagdon Morgan. Baltimore: William Wood & Company, 1938.

In the foreword of this interesting book by an English physician there is a quotation from Dr. Samuel Tuke of York Retreat, written in 1841, in which he gave credit to Sir William Ellis for introducing work on a large scale to asylum patients in England well over a century ago. But to Dr. Simon of Gutersloh is given the credit, early in this country, for using work as a "soothing potion in the hands of every nurse."

The purposes and aims of occupational therapy are discussed in the introduction. These deal freely with human nature, especially as it may react to success or failure. The value of work treatment does not depend on the quality of the thing made but more on the favorable reactions of the patient. The ability to work is usually a more wholesome commentary on recovery from fatigue than almost anything else that may happen.

Under psychologic types, motives for work are discussed—among others to serve, to delight, to rule. Some handle material things, as a curator; some work with symbols, as the clerk; others tend animals, such as fanciers; some serve human beings, as nurses. Interesting case histories of various clinical reaction groups are presented to demonstrate how work has blended into the lives of patients to alloy a better compromise between health and disability. In many respects the chapter on the prescription is the most interesting. Physicians gen-

erally do not give sufficient thought to the purpose of work to formulate a satisfactory program. An ingenious form is presented enabling a prescription to be written in code form covering aims to be achieved and dangers to be avoided.

The author discusses the degree of specialization among therapists found in Germany, the Netherlands and the United States. He leads one to believe that occupational therapy should be less specialized and more a part of the regular nursing regimen. It is refreshing to know that occupational therapy embraces a great variety of work, games, hobbies, dancing, entertainments and reactional activities indoors and out, including habit training. Spontaneity is emphasized. Formalism is decried. Work for the institution is no less valuable than anything else. Whether it should be centralized or scattered depends on local conditions, but in general there should be a well recognized headquarters for work. Some chapters are devoted to special buildings and facilities, the care and selection of supplies, and the choice of designs. Short chapters devoted to individual crafts give a simple statement of essential needs.

A chapter or two correlating work therapy with psychotherapy and hydrotherapy would have added to the value of the book; also a follow-up study to ascertain what place occupational therapy holds in the retrospective memory of socially adjusted patients.

The book is well written and illustrated and has much in it that commends itself to psychiatrist, nurse and occupational therapist, whether these are separate persons or one.

**Eine experimentelle Studie über Calciumoxalat als Steinbildner in den Harnwegen: Speziell mit Rücksicht auf die Bedeutung des Magnesiums.** Von Greta Hammarsten. Aus dem medizinisch-chemischen Institut der Universität Lund. Paper. Pp. 155, with 40 illustrations. Lund: C. W. K. Gleerup; Leipzig: Otto Harrassowitz, 1937.

This is a monograph in which the role of calcium oxalate in relation to stone formation in the urinary tract is exhaustively studied. Many tables are presented in demonstrating the physical properties of calcium oxalate in relation to solubility. The various effects of magnesium intake and urinary magnesium excretion on the formation of calcium oxalate stones are forcefully stressed. In animal experiments using rats, stone formation was frequent when the urinary magnesium excretion was lowered with coincidental increased calcium and oxalic acid excretion. However, if vitamin A and D deficiency was added to the foregoing conditions, stone formation was still greater and damage to the renal parenchyma more marked. An acid producing diet reduced definitely the incidence of stone formation. The frequency of stone formation in a large series of animals was greater in the male, coinciding with a higher urinary calcium output in the male sex. Males showed in general a higher urinary calcium excretion. It is interesting to note that on a vitamin poor diet with very low magnesium intake the incidence of stone in the female approaches that in the male. The view that protective colloids have no demonstrable part in the prevention of stone in either sex is maintained. Experimental stones were decalcified when the diet was changed to include adequate vitamins, calcium and magnesium, provided the renal parenchyma had not been too badly damaged. The more important clinical conditions under which calcium metabolism may be disturbed, often with increased urinary calcium excretion, are (1) calcium deficiency, (2) magnesium deficiency, (3) acidosis, (4) avitaminosis A, B, C and D, (5) hypervitaminosis A and D, (6) hyperparathyroid and hyperthyroid function, (7) intestinal diseases in which the absorption of the necessary minerals and vitamins is impaired, and (8) skeletal trauma of considerable extent. Stress is laid on the fact that even with a large intake of calcium and magnesium, unless they are in a readily absorbable form, deficiency of these substances will be evident. It is erroneous to assume that calcium containing foods are to be avoided in the presence of calcium stones. If sufficient calcium in an easily absorbable form, the best of which is milk, is maintained in the diet, along with an adequate magnesium and vitamin intake, a calcium balance is maintained, keeping the excretion of calcium in the urine very low. Conversely, a paradoxical increase in calcium excretion in the urine can be maintained by too

low a calcium intake with a concomitant deficiency in fat soluble vitamin ingestion. Foods rich in oxalic acids, which are tabulated, should be avoided. A bibliography which includes more than 300 references is included in this excellent work.

**A Textbook of Physiology.** By William D. Zoethout, Ph.D., Professor of Physiology in the Chicago College of Dental Surgery (Loyola University). Sixth edition. Cloth. Price, \$4. Pp. 714, with 291 illustrations. St. Louis: C. V. Mosby Company, 1938.

This edition of a popular intermediate textbook in physiology is in several respects an improvement on previous ones. The hormones and vitamins are more adequately treated than before. The section on higher central nervous system activity is particularly clearly written. The occasional phonetic analysis of words, as on page 170, is, however, of questionable propriety. A student sufficiently advanced to read the book should be acquainted with such words. A number of illustrations of out of date apparatus are still included, for example one of Dudgeon's sphygmograph. In general the illustrations are well selected and competently reproduced. There is a twenty page index which is well organized. A particularly distressing thing about the book is that the publisher's "blurb" on the jacket is a model for rhetorical errors and is in bad taste generally. Such statements as "In fact the entire make-up of the book was that good that it was used in schools in every state in the country with the exception of one" might easily deter one from looking seriously at the book itself.

**The Living Body: A Text in Human Physiology.** By Charles Herbert Best, M.A., M.D., D.Sc., Professor and Head of Department of Physiology, University of Toronto, Toronto, Canada, and Norman Burke Taylor, M.D., F.R.S., F.R.C.S., Professor of Physiology, University of Toronto, Toronto, Canada. Cloth. Price, \$3.60. Pp. 563, with 283 illustrations. New York: Henry Holt & Company, 1938.

This book was written for the college student and the inquiring layman and, as far as textual material and information go, is but another textbook since it does not present any particularly new approach or any original point of view over any of those in the several textbooks now available. The information is conventionally sound and simply presented. Illustrations cover much the same ground as found in any good textbook, although many are original; others were taken from well recognized and authoritative sources, all of which are acknowledged in the preface. These critical statements need not be interpreted as derogation, for the work is unquestionably valuable, but rather as decrying the current tendency to produce more and more textbooks for which there is no real demand and which do not offer any improvement over many of those already available. Taken alone, there is nothing to criticize in this book. Taken with other current textbooks, there is nothing in particular to praise.

**The Hypothalamus: Morphological, Functional, Clinical and Surgical Aspects.** By W. E. Le Gros Clark, D.Sc., F.R.C.S., F.R.S., John Beattie, M.D., D.Sc., George Riddoch, M.D., F.R.C.P., and Norman M. Dott, F.R.C.S. Ed. The Henderson Trust Lectures, Nos. XIII-XVI, published for the William Ramsay Henderson Trust. Cloth. Price, 12s. 6d. Pp. 213, with illustrations. Edinburgh & London: Oliver & Boyd, 1938.

This book, which is attractively bound, is printed on excellent paper and is well illustrated and contains four lectures which comprise the Henderson Trust Lectures delivered in Edinburgh in October 1936. The lectures have been enlarged to bring down to date the knowledge concerning the morphologic, functional, clinical and surgical aspects of the hypothalamus. Every one interested in organic neurology, endocrinology and neurosurgery will find this a comprehensive review of the subject. It is written by men who are well qualified; the authors admit our limited knowledge but present clearly and concisely what is known. The anatomic relations of the hypothalamus are described and a comparison between man and lower mammals is used to emphasize similarities and differences. The lecture on the functional aspect of the hypothalamus is of clinical interest, as it is divided into sections dealing with known physiologic evidence pointing to definite functions. The lecture on the clinical aspects of hypothalamic derangement outlines the so-called 'hypothalamic syndrome,' consisting of obesity, amenorrhea, diabetes insipidus, glycosuria and disorders of sleep. The

intracranial diseases which give rise to the hypothalamic syndrome are also described and discussed. Closely related to the clinical presentation is the lecture on the surgical aspect of the hypothalamus, in which cases are presented, with roentgenograms of the skull, ventriculograms, reproductions of photographs of the patients and drawings of the tumors found at operation. When the book has been read, one feels that the subject has been clearly, concisely and comprehensively presented in such a manner that every practitioner of medicine interested in the subject should consider it for his book shelf.

**The Construction of Vulcanite Applicators for Applying Radium to Lesions of the Buccal Cavity, Lips, Orbit and Antrum.** By Desmond Greer Walker, M.A., M.Dent.Sc., M.B., Assistant Dental Surgeon to the Royal Dental Hospital, London. Foreword by W. Warwick James, O.B.E., F.R.C.S., L.D.S. Published for the Middlesex Hospital Press. Cloth. Price, 5s. Pp. 61, with 23 plates. London: John Murray, 1938.

The treatment of malignant diseases of the mouth requires very accurate application of radiation, especially when it is applied in the form of radium therapy. Without mastery of the necessary complicated technic its imperfect use has in the past resulted in definite damage to the bone. This type of injury may now be avoided by the use of protective shields. This monograph is offered by the author as the outcome of experience gained through three years of radium work at the Middlesex Hospital in London. The employment of vulcanite applicators is carefully described, and for physicians working in radium therapy it should prove exceedingly helpful. These applicators afford a means of applying radium to sites which were previously impossible to treat, for instance the neighborhood of the anterior pillar of the fauces. The method offers a great improvement in accuracy over previous technics, and better protection for the surrounding tissues is possible by incorporating lead in the applicator.

### MEDICOLEGAL ABSTRACTS

**Workmen's Compensation Acts: Enucleation of Eye Resulting from Exposure to Light Incident to Electric Welding.**—The claimant, in the course of his employment as a ship fitter, for several periods of from one-half hour to one hour each, Dec. 28, 1934, was exposed to the bright glare of light incident to electric welding machines. He did not wear goggles or eye protectors. He was not engaged in the operation of the machines but his work took him into their vicinity. On the day when this happened he had a "grippy" feeling but he worked all day. His eyes, he claimed, were normal except that he had to use glasses to read or draw on blueprint, but then he used only ordinary reading glasses. On previous occasions when he worked with or close to electric welding machines he had suffered some irritation of the eyes, but on this day he felt no discomfort until on his way home after work. Then his eyes "felt like some one would take a handful of sand and throw it in your eyes and cause your eyes to water all the time." When he reached home his wife sent for the family physician. She made a potato poultice to ease the irritation of the eyes. Not because of any condition of his eyes, but because he was not responding satisfactorily to the treatment for grip, a second physician, Dr. Jameson, was called in. He, however, noticed the home made remedy applied to the eyes and ordered it discontinued, suggesting the use of mild protein silver and boric acid. As the eyes got no better an eye specialist, Dr. Semeley, was called January 4. Dr. Semeley saw the claimant again January 7 and instructed him to go to the Wills Eye Hospital. There he was treated by Dr. O'Brien, and after several weeks of observation and treatment Dr. O'Brien enucleated the claimant's left eye.

Claiming that the loss of his eye was due to exposure in the course of his employment to the flashes of electric light caused by the electric arc welding machines, the claimant instituted proceedings under the workmen's compensation act of

New Jersey. A referee for the workmen's compensation bureau denied him compensation. The claimant thereupon appealed to the court of common pleas of Camden County, which reversed the finding of the referee and awarded compensation. The claimant's employer then appealed to the supreme court of New Jersey.

Dr. O'Brien, who had treated the claimant in Wills Eye Hospital and who had enucleated his eye, testified that the claimant had suffered from panophthalmitis, which he described as an inflammation of all the structure of the eye from "within out." In his judgment the flashes of light from the electric welding had irritated the eyes of the claimant and caused him to rub them. By rubbing them he started up virulent organisms or sources of infection, present in almost every eye, and they "broke through" the front of the eye and infected the entire organ. In Dr. O'Brien's opinion the infection did not come from within the eye or from any source back of the eye; after removing the eyeball he had examined the eye socket and found no pathologic change in its bony framework. The infection did not come from the sinuses. Dr. Shemeley, who saw the claimant only twice, January 4 and January 7, testified on behalf of the employer. Although the claimant's exposure to the flashes from the electric welding process occurred on December 28 and this witness did not see him until January 4 and although the witness admitted that it was possible for a "flash burn" to clear up in twenty-four hours, he testified that in his opinion the condition of the claimant was not due to a flash burn. In the opinion of this witness the claimant's exposure to the flashes of light from a welding machine would not have any effect on his eye.

Another medical witness on behalf of the employer, who examined the claimant April 12, some months after the eye had been removed, and who based his opinion on symptoms and conditions stated in the notes made by Dr. Shemeley on the two occasions on which he saw the claimant, was of the opinion that the infection came from within and was not the result of the exposure to the flashes of light incident to electric welding.

In summing up, the supreme court emphasized strongly the differences in the opportunities that the several expert witnesses whose testimony is referred to had had for becoming personally acquainted with the condition of the patient. Dr. Shemeley had seen the patient only twice, "on both of which instances the organ was in a very distressed condition." Dr. Dublin's testimony was predicated on an examination made a considerable time after the claimant's eye had been removed and rested in the main on charts prepared by Dr. Shemeley. Dr. O'Brien saw the claimant daily for weeks, then removed the eyeball, and thereafter kept the claimant under observation. It is not necessary, said the court, for the claimant to carry the burden of proof to the point of demonstration. It is sufficient to show that the hypothesis on which he based his claim is probable, and this, the court thought, the claimant had done. For that reason the judgment of the court of common pleas of Camden County in favor of the claimant was affirmed.—*Jackson v. New York Shipbuilding Corporation* (N. J.), 197 A. 284.

**Dental Practice Acts: Suspension of License for Conviction of Crime; Subsequent Good Conduct as Mitigating Circumstance.**—Brown, a licensed dentist, was convicted of manslaughter and sentenced to pay a fine and serve a jail sentence. The jury recommended clemency and he was thereafter paroled. About a year and a half later, the board of governors of the registered dentists of Oklahoma suspended Brown's license under a provision of the dental practice act authorizing the board, on presentation of a certified copy of a court record showing that a licentiate has been convicted of a crime involving moral turpitude, to revoke his license or to suspend him from practice or to reprove him. Brown appealed to the Supreme Court of Oklahoma.

The evidence showed that Dr. Brown had practiced dentistry since 1911, that he had always borne a good reputation, that he was a man of good morals and high character, that the only blemish on his record was the act which formed the basis of

his conviction, and that subsequent to the conviction he bore a good reputation and maintained a high standing of character. One who has practiced his profession for twenty-three years, said the Supreme Court, maintaining at all times an excellent reputation and being in fact a man of high character, but who then is guilty of such an act of moral turpitude as was here charged against Brown, may thereafter so conduct himself by right conduct in his profession and as a citizen as to reestablish himself as a man of high character. This, in the opinion of the court, Dr. Brown had done. The board seemed to have concluded that the conviction required it to take disciplinary action without regard to the fact that subsequent to the conviction the dentist had conducted himself above reproach. That view, the court said, while doubtless entertained in good faith, was erroneous and in law constituted an abuse of discretion on the part of the board. The Supreme Court accordingly reversed the decision of the board suspending Brown's license to practice dentistry.—*Board of Governors of Registered Dentists of Oklahoma v. Brown* (Okla.), 76 P. (2d) 1074.

*Fifth Annual Meeting and Seventh Conference on Rheumatic Diseases, held in San Francisco, June 13, 1938*

LORING T. SWAIM, M.D., Boston, Secretary

#### Radiculitis Associated with Spinal Arthritis

DR. WILLIAM J. KERR, San Francisco: The radicular syndrome has been described as a symptom complex associated with hypertrophic spondylitis or osteo-arthritis of the spine. The symptoms are related to local inflammatory or degenerative processes in the spinal column adjacent to or involving the nerve roots, causing sensory and motor disturbances of radicular distribution. In some cases the autonomic nerves are affected. The symptoms are dependent on movements of the spine, relaxation of the supporting spinal structures or circumstances which cause an increase in the intraspinal pressure. Among these are the acts of coughing, sneezing or straining at stool (Dejerine's sign).

The symptoms are referable to the nerves emerging from the spinal axis. Disturbances in sensation, spasm of muscles with limitation of motion of the spine and atrophy of skeletal muscles are of common observation. These changes are evidently related to injury of the skeletal nerves. Other disturbances in the viscera and to the vessels of the trunk and extremities are related to injury of the autonomic nerves supplying these structures. Vascular symptoms in the extremities may precede swelling in the joints in some cases, suggesting that the involvement of the joint is likewise due to irritation of sympathetic nerves at the spinal axis. Any segment of the body may be affected. Those regions from which the nerves supplying the extremities emerge from the spine appear to be most frequently involved. Perhaps this is only because we are more able to recognize the patterns of symptoms related to lesions in these regions.

Altered sensations are commonly observed. Hyperesthesia or hypo-esthesia to light touch (cotton wool), to painful stimuli or heat and cold may be demonstrated by careful study of the segments involved. Pain or tenderness on pinching of the skin

may help to localize the radicular area affected. Hypertonus of the muscles in the early stages and hypotonus or atrophy in the late stages may be helpful. Any condition which increases the intraspinal pressure, e. g. pressure on the jugular veins (the Queckenstedt test) or coughing, sneezing or straining at stool, may reproduce the symptoms. This test thus is not a differential test from tumor of the spinal cord or nerve roots. The pain may be relieved by vasodilators such as amyl nitrite or glyceryl trinitrate and thus with pain simulating angina pectoris the differentiation cannot always be made by these drugs. If the symptoms are abdominal one may put the abdominal muscles on tension, and tenderness on palpation will disappear, whereas in peritonitis the tenderness will persist.

The segmental areas involved will generally direct attention to the segments of the vertebral column which are involved. Local tenderness of the spine, pain on motion and stiffness of the spinal column may be found if the process is active or recent, or rigidity may exist without other signs if the process is quiescent. Films of the spine may show few changes early when symptoms are acute but generally there is some evidence of changes in shape or density of the bodies of the vertebrae or intervertebral disks, some fuzziness or narrowing of the foramina, or spurring of the margins of the vertebrae or the articular facets with the ribs. Changes in the spinal curves and scoliosis may be shown best by films. In some cases marked osteo-arthritis changes are shown by x-ray examination when there are no symptoms. Almost invariably there are detectable signs and the patient has forgotten the acute manifestations.

The treatment is effective in many cases. In patients whose occupations place undue strain on certain parts of the spine, some relief may be obtained by changing to another occupation which puts less strain on the spine. The most frequent contributing factor is distortion of the spinal column by excessive weight on the trunk. The pendulous abdomen accentuates every curve. The lower lumbar and lumbosacral and sacro-iliac joints suffer most but compensatory changes in the upper thoracic and cervical spine usually give symptoms in the upper extremity or in the upper cervical region, with frequent radicular symptoms in the occipital region. Abdominal support and dietary management frequently relieve the symptoms in this group.

Temporary symptomatic relief may be obtained from drugs (salicylates) or from local heat, which may be moist heat, radiant heat, electric pad or the use of a hot electric iron or flat iron moved back and forth along the spine over several thicknesses of a bath towel. Gentle massage and manipulation may be helpful. In some cases of cervical arthritis, stretching of the neck may be resorted to with great relief. Other more radical measures are generally unnecessary. Violent manipulations have been known to cause fractures of the vertebrae or their processes and therefore those who practice spinal adjustments should be avoided. The orthopedists are learning to treat these patients more rationally and often with great benefit, but other specialists in the surgical field have much to learn about the diagnostic features of the syndrome. The abdominal scars, often multiple, seen on many of these patients bear testimony to hasty judgment in the interpretation of symptoms.

#### Nonrheumatic "Growing Pains" and Subacute Rheumatic Fever

DR. M. J. SHAPIRO, Minneapolis: Painful extremities in children have been given a variety of names, such as growing pains, muscular rheumatism and muscle and joint pains. In a number of recent articles from 8 to 50 per cent of children considered as rheumatic have been so diagnosed on the basis of pain in the extremities alone. Actually, an analysis of the histories of 100 of the patients with well developed rheumatic heart disease at the Lymanhurst Health Center reveals that 84 per cent of them gave a definite history of a major attack of rheumatic infection: either rheumatic fever or chorea, or both. A critical study of the remaining 16 per cent demonstrates that in practically every instance, in spite of the fact that no history of a major attack of rheumatic infection was obtained, there was definite evidence that they were suffering from a long continued rheumatic infection. They presented the well known signs and symptoms of chronic rheumatic infection, such as low grade fever, loss of weight, definite joint pains, nosebleeds, skin

rash, increased sedimentation rate and pallor, although their symptoms were not severe enough to put them to bed.

A follow-up study on 200 children who complain only of leg pains has been carried out at the Lymanhurst Heart Clinic for the past three years. None of them have presented any evidence of chronic rheumatic infection. They complain of pain primarily in the lower extremities. The pain comes on commonly at the end of the day and often awakens the patient during the night. They rarely complain of pain during the day and practically never have symptoms in the upper extremities. They are usually in good health otherwise, and none of them have developed rheumatic heart disease. Laboratory studies of these patients give normal results. This syndrome is so common in healthy school children during early childhood and adolescence that it is suggested that their complaint is due to normal growth. It is clear that they are not suffering from rheumatic fever and should not be so considered.

Many children with growing pains alone have been subjected to tonsillectomy, sinus drainage, periods of rest in bed, vaccine treatment, and so on on the erroneous conception that they were suffering from rheumatic fever. It would appear that the old idea that normal growing children do suffer from growing pains is probably correct. Much of the confusion could be avoided if the term "growing pains" was not used in connection with rheumatic fever.

#### DISCUSSION

DR. T. DUCKETT JONES, Boston: This report should do much to clear up the vagueness which exists concerning the joint manifestations of rheumatic fever. Especially harmful has been the attempt to label a child as prerheumatic with little or no justification. The absence of a specific diagnostic test is the cause of the difficulty. The development of heart disease of the rheumatic type is the most definite existing proof that a child has had rheumatic fever. In my experience, definite arthralgia has occurred at some period of active rheumatic fever in fully 70 per cent of a large series. The type of pain has been well described by Dr. Shapiro. Joint symptomatology may be real, but it is rarely of a chronic nature, and other features are much more significant. I should heartily agree with Dr. Shapiro that so-called growing pains in a child, without a frank history of previous rheumatic fever, do not frequently occur with other manifestations of rheumatic fever or a tendency to develop subsequent rheumatic heart disease. This has proved to be true even in families in which there are one or more definite rheumatic fever subjects. It is common today to see definite rheumatic fever with the development of rheumatic heart disease, without joint symptomatology, at the time of acute illness. Abundant clinical and laboratory evidence supports this view. In the carefully followed rheumatic child, mild to severe acute illness is almost invariable, and vague syndromes rarely exist. The insidious or asymptomatic development of rheumatic heart disease in children is uncommon, but in the young adult it is observed. This demonstrates that silent rheumatic fever does exist, but in following such a group I have been impressed with the frequency with which abnormal laboratory data are found either by electrocardiogram or by such nonspecific measures as the white blood count or sedimentation rate. Dr. Shapiro has noted that these tests are normal in children with growing pains, and this would seem significant to me. I should like to ask Dr. Shapiro whether he has followed any appreciable number of children with vague muscle aches and pains for a significant period of time? Dr. Shapiro's differentiation is not only important to the problem of the individual child but should help us in the broader aspects of the problems of rheumatic fever. Especially, it should help prevent the partial invalidism and even institutional care of a large group of children so often mistakenly thought to have rheumatic fever.

DR. J. ALBERT KEY, St. Louis: I am glad that the growing pains are coming back again. I have told the parent "this child has growing pains" and had them reply "I am sorry, but my doctor tells me that growing pains are old fashioned and they don't have them any more." As a matter of fact, people do have growing pains. Most growing pains, I think, are not to be classed as epiphysitis but as epiphysal strains. It is also conceivable, as Dr. Hitchcock just suggested to me, that growing pains are due to a strain of muscles: bones may grow faster

than muscles and fascia and cause strains at the muscular attachments. A third explanation is that they may be due to actual stretching of the nerves due to rapid growth of bones.

DR. M. HENRY DAWSON, New York: Could it be found whether an actual quantitative study has been done on growth during that period in which growing pains occur? Do the pains occur most frequently in individuals who grow most rapidly?

DR. FRANKLIN R. NUZUM, Santa Barbara, Calif.: As an index of how prevalent the belief is that growing pains in children do mean rheumatic fever, I reviewed six current medical textbooks and found that three of them stress the importance in the history of the occurrence of so-called growing pains in arriving at a diagnosis of rheumatic fever. Dr. Shapiro, on the other hand, has shown that among his own patients this type of pain occurs in healthy growing children. He has further substantiated his argument by following for a period of years a group of children that were referred to him with a diagnosis of rheumatic fever and whose chief complaints were "growing pains." He found that other symptoms of rheumatic infection did not develop: laboratory tests were negative, their symptoms continued to or through adolescence and disappeared, and further repeated examinations after a period of years demonstrated that rheumatic heart disease had not developed in any of this group. The latter is a most convincing point, since approximately 75 per cent of children with rheumatic infection do develop clinical evidence of heart disease. Just as it is incorrect to attach the stigma of rheumatic fever to a child who complains of muscle pains occurring especially at night, so is it incorrect to give the name rheumatic fever to the secondary arthritides that may complicate scarlet fever, pyemia, cerebrospinal fever, dysentery and other acute infectious diseases. When a single articulation is affected in a child, the condition rarely is due to rheumatic fever. The same is true of the disorder of more than one joint that remains stationary for many days, especially in the first attack. The intervertebral articulations are seldom involved in rheumatic fever but often are involved in tuberculosis and gonorrheal infections. It is generally believed that every child who has rheumatic fever suffers some damage to the heart. In about 75 per cent the degree of inflammation is sufficient to result in evident damage to the valve leaflets, the heart muscle or both. In those instances in which physical examination does not elicit evidence of heart damage, an electrocardiogram may be used as an aid in making the differentiation between rheumatic fever and recurring muscular pains of other etiology. In the former, abnormal curves are obtained in about 90 per cent; in the latter, normal curves are usually found. The abnormal electrocardiograms present a variety of changes; among them, a delay of conduction time between auricle and ventricle, abnormalities of the P or auricular wave, and/or of the RS-T or ventricular segment. The importance of an accurate history as an aid in arriving at a diagnosis of rheumatic fever bears emphasis. Dr. Shapiro has implied that this part of the study should not be detailed to a nurse assistant or an intern but should be carried out by the physician himself.

DR. M. J. SHAPIRO, Minneapolis: I have consulted a number of investigators interested in the study of growth and have tried to get an opinion on this subject. They all agree that normal growth might possibly produce such symptoms but they would not commit themselves. I have made no claim that this clinical entity is due to growth. I suspect that it is, because it is so common. Those of us who have been working on the subject of rheumatic fever are, I believe, responsible for most of the errors that are made. We have carried on propaganda for many years to impress the public with the idea that there was no such thing as "growing pains," that growth was painless, and that "growing pains" in most instances were manifestations of rheumatic fever. As Dr. Key has stated, many children with "growing pains" are referred to private physicians and clinics with a previous diagnosis of rheumatic fever. In answer to Dr. Jones's question as to how long these patients had been followed, I may state that this study was set up three years ago. All patients with "growing pains" who in my opinion were not suffering from rheumatic fever have been included in this group. The clinical picture is so similar that statistical study seems hardly necessary although it is admitted that these patients have not been followed long enough. Up to the present time, none

of them have developed rheumatic heart disease. As Dr. Dawson has pointed out, it will be of considerable interest to determine whether or not these children have most of their symptoms during the period of most active growth. Such a study is now being carried out.

#### Metabolic Factors in the Induction of Carditis

DR. MARK P. SCHULTZ, Washington, D. C.: Nonpurulent carditis was induced in rabbits and guinea pigs subject to chronic focal, hemolytic streptococcus infection while being treated with moderate doses of thyroid; suitable controls were negative. When dinitrophenol was substituted for thyroid under similar conditions, no cardiac lesions resulted. In guinea pigs affected with chronic focal infection while receiving maximum tolerated doses of insulin, valvular and myocardial lesions developed similar to those observed in infected, scorbutic animals: the association here of scurvy as a complicating factor was improbable. An attempt was made to determine which of several attributes of the scorbutic state are factors in the development of nonpurulent carditis during the course of associated focal infection; viz., acidosis, adrenal damage or increased metabolic rate. The hearts of guinea pigs with chronic focal infection forcibly fed large doses of acidic salts were negative. No cardiac lesions were observed in adrenalectomized rats with chronic focal infections. The nonpurulent carditis observed in infected guinea pigs with chronic scurvy was of greatly increased incidence and severity in such animals treated concurrently with ultraviolet irradiation to enhance further their metabolic rate above that degree of elevation associated with uncomplicated scurvy. The increased metabolic rate in scurvy is probably a factor in the induction of nonpurulent carditis during the course of infection.

These experiments demonstrated that the induction of various metabolic anomalies in experimental animals during the course of chronic focal infection conduces to the development of nonpurulent carditis. In this connection the possible significance was suggested of the relatively frequent development of rheumatic fever and exophthalmic goiter in the same individuals and the cessation of rheumatic fever activity in those patients developing diabetes.

#### DISCUSSION

DR. K. K. SHERWOOD, Seattle: These experiments show that part of the result is due to the metabolic state of the animal at the time of the experiment. I should like to ask the author whether he subscribes to the view that this increased metabolic rate automatically increases the vitamin C requirement. In relating these experiments to the clinical problem, the question arises as to the absorption of the available dietary vitamin C. We know that human beings with atrophic arthritis and rheumatic fever frequently require an extremely high vitamin C intake for a long time before it becomes reflected in the blood level. The third question concerns edema in low vitamin C states. It seems to me that part of the therapeutic effectiveness of vitamin C lies in a partial control of edema in certain rheumatic states.

DR. JAMES F. RINEHART, San Francisco: The interpretation of Dr. Schultz's experiments is not easy. The production of a carditis in rabbits and guinea pigs treated with thyroxine or thyroid substance and subjected to streptococcal infection is probably explainable on the basis of an induced vitamin C deficiency incident to the action of the thyroid substance. Schuelter found that thyroid depleted the organ content of vitamin C while dinitrophenol did not have this effect. If the augmentation of the nonpurulent carditis of scurvy and infection by irradiation induces a hyperthyroid state with the increased activity of the heart, one would expect an augmentation of the carditis. The possibility of irradiation introducing another toxic influence must be borne in mind. The experiments with insulin are more difficult to interpret. However, it would appear pertinent to investigate the effect of prolonged large doses of insulin on the vitamin C metabolism. I believe the induced cardiac pathologic conditions in this series of experiments was less striking than in the thyroid experiment and I am not agreed that they resemble those of rheumatic fever as closely as those of scurvy and infection. In my experience significant cardiac lesions resulted only from the combined influence of infection (chiefly of the hemolytic streptococcus type) and vitamin C deficiency and rarely if at all in uncomplicated vitamin C

deficiency. The experimental production of a carditis and arthritis and the occasional development of subcutaneous nodules affords an unusually broad experimental basis for the thesis that vitamin C deficiency enters in the etiologic mechanism of rheumatic fever. Metabolic studies indicate that depletion of vitamin C is the rule in rheumatic fever. The concept that vitamin C deficiency contributes to the etiology of rheumatic fever has as yet been inadequately investigated in the clinic. Well controlled and prolonged therapeutic and prophylactic experiments remain to be done and to me appear clearly indicated.

DR. J. ALBERT KEY, St. Louis: Since it is conceded that with infection there is an increased demand for vitamin C, it is possible that here the infection may be the primary factor. It also appears to me that possibly the thyroid which was given acted as a direct toxin on the heart and that the reason these animals developed carditis was that their heart was damaged and the organisms attacked the point of lowered resistance. It is also important to know what other lesions these animals had in addition to their carditis. It may be that these experiments reduced their general resistance much as Pasteur did when he had his chickens stand in cold water. Finally it should be pointed out, as Kinsella noted last year before the Association of Physicians, that the primary lesion in rheumatic fever is not a purulent lesion. There is considerable difference between the primary lesions in rheumatic fever and the primary lesion induced by any known streptococcus. In a streptococcal infection the primary cell reaction is a polymorphonuclear leukocyte infiltration in the damaged area and, as I understand it, in rheumatic fever this does not occur. I don't think that we have the right to correlate a late fibroma induced by any means whatever with rheumatic fever because it resembles a late rheumatic lesion.

DR. T. DUCKETT JONES, Boston: Dr. Schultz's work has been presented in a straightforward manner, and no involved claims concerning etiology were made. A most salutary phase of the work is that it carries to the laboratory some of the features observed in patients with the disease in question. It should stimulate further attempts to reproduce rheumatic fever experimentally by means of variations and features observed at the bedside. There has been a tremendous amount of experimental work with streptococci in the past forty years, without any proof that any form of streptococcus is the cause of rheumatic fever. This should not only make us critical of any new theories but spur us on to renewed effort along lines at variance with ordinary accepted ideas. It is pertinent to mention the work of Dr. Rinehart and his co-workers on the possible role of vitamin C in rheumatic fever. In our experimental studies with guinea pigs the same lesions were found in animals with acute scurvy as in those with chronic scurvy and superimposed streptococcal infection. It has seemed to us that the streptococcal infection produced a complete scorbutus and that this was responsible for the lesions in the guinea pig heart. Dr. Schultz has told me that he has been unable to confirm this observation and suggests as a reason the frequent finding of an unsuspected streptococcal infection in guinea pigs kept in the laboratory. This is a possibility, but more important would seem to be the distinct variations in diet used. It may be well to add a further word of caution concerning vitamin C, since it has been mentioned freely and may well be important in rheumatic fever. My remarks concern the obvious pitfalls in considering such features as the geographic distribution and seasonal incidence of rheumatic fever as furthering any particular etiologic hypothesis. The geographic incidence of rheumatic fever is unknown. We speak glibly of its absence in the South, and yet every intelligent survey in areas where the disease is thought to be nonexistent indicates the fact that the disease is present, though it may be uncommon. Just recently in southern Florida I have seen a number of natives with definite rheumatic fever. In this area fruit is cheap and sunshine abundant. Also hemolytic streptococcus infections in this area are uncommon. We have streptococcus immune body studies on a group in this community, and although respiratory infection is common, specific hemolytic streptococcus immune bodies rarely develop. It is not entirely reasonable, therefore, to consider the availability of inexpensive

vitamin C and the geographic distribution of rheumatic fever as necessarily being important from an etiologic point of view.

DR. DAVID FERGUSON, Bremerton, Wash.: Dr. Key brought up an important point in asking whether the pathologic condition found in the hearts of the animals that had thyroxine was not due to thyroxine rather than to infection. McEachern and his associates have definitely shown that focal necrosis as the pathologic lesion in thyroid heart disease does not occur. In fact, no anatomic changes occur in the heart as the result of hyperthyroidism. Dr. Schultz seems to show that there is some curious synergistic effect resulting from the combination of infection and thyroxine.

DR. MARK P. SCHULTZ, Washington, D. C.: I wish to emphasize the comment of Dr. Jones that the experimental lesions which have been described are not presented as those of rheumatic fever, although in my opinion they do somewhat resemble them. Concerning such experimentally induced lesions the conception is, of course, offered that the human disease is actually reproduced and that the failure to duplicate it actually is due to species differences in reactivity. It is doubtful that on the basis of the evidence at present available such a conclusion may be reached with respect to the observations which have just been presented. Dr. Sherwood has pointed out that coincident with an increased metabolic rate the vitamin C requirements of the organism are increased and that consequently the pathologic changes which were induced may have been occasioned by concomitant scurvy. In rabbits treated with thyroxine the validity of such a conclusion seems improbable, as this species belongs to the group not susceptible to such nutritional deficiency. The guinea pigs treated with insulin, it should be emphasized, received sufficient ascorbic acid subcutaneously to protect them in event of a complete absence of this vitamin from other sources against all the manifestations of scurvy except the microscopic tooth changes. In addition, because their appetites were inordinately increased and cabbage was liberally supplied in measured quantities, they are known to have consumed from eight to ten times the amount of vitamin C which has been found adequate to protect such animals against scurvy when no other source of the vitamin is present. The same is true of the rabbits and guinea pigs treated with thyroxine or desiccated thyroid gland. Dr. Heninger and others have recalled the fact that cardiac lesions resembling some of those which have been described here have been reported induced in experimental animals merely by treatment with thyroid and suggest that the results which have just been outlined were possibly due to an uncomplicated toxic effect of thyroid. I feel that this is unlikely for two reasons: First, a detailed study of the literature bearing on this point brings to light the fact that in most papers reporting the induction of damage to the heart through action of an excess of thyroid alone it is also reported, without particular significance being attributed to the circumstance, that accidental infection was present in the animals under observation. In studies such as those of Rake and McEachern, in which the presence of infection is rightly excluded during the period of thyroid treatment, no cardiac damage is observed. Second, the hearts of our control animals which received thyroid but were not infected were essentially normal. Dr. Jones and his colleagues and others have recently reported the development of cardiac lesions in guinea pigs of the type originally described by Dr. Rinehart and his associates, and of that under discussion here, in animals subject to scurvy not complicated by infection. My experience has been to the contrary, for the hearts of guinea pigs dying from the effects of scurvy have been essentially normal in those instances in which the presence of infection could be excluded with certainty. The wide prevalence of spontaneous hemolytic streptococcus lymphadenitis in guinea pig stock is probably responsible for the difficulty on this point. It has been my experience that positive cultures may be obtained from subcutaneous areas in the cervical, inguinal and axillary regions in many instances in which cultures of the blood and various internal organs are negative. Unless cultures are made from the parts mentioned it is improbable that the presence of infection can be excluded without question.

(To be continued)

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

**Aluminum Hydroxide Gel in Peptic Ulcer.**—Emery and Rutherford used colloidal aluminum hydroxide in the treatment of eight cases of the severe type and four of the moderately severe type of peptic ulcer. Five of the patients were treated by the drip method and seven by the oral method. Those patients who started on the drip method were shifted to the oral method after one week. A solution of one part of the aluminum hydroxide (creamalin) to three parts of water was used at all times. The amount which was used varied slightly, but on the average 15 drops per minute was allowed to drip through the tube. It was given orally in amounts of 60 cc. of the mixture per dose. A dose was given every hour from 8 a. m. to 9 p. m. In addition to the aluminum hydroxide, the patients were fed according to the schedule outlined by Sippy. All patients were relieved of pain due to the ulcer within twenty-four hours and had no recurrence of pain while remaining on the treatment. Colloidal aluminum hydroxide in addition to neutralizing the secreted acid decreases the titratable acidity of the gastric juice. Oral administration of the drug produces a somewhat slower decrease in the titratable acidity, which ultimately reaches the same general level. All patients who fail to respond satisfactorily to the Sippy regimen should be treated with aluminum hydroxide before surgical intervention is carried out. Colloidal aluminum hydroxide is also useful for treating ulcer patients who show a tendency to form renal calculi. The drug is absorbed but slightly and does not interfere with the acid base balance. It proved to be useful in treating four patients who had nephrolithiasis.

**Ascorbic Acid and Peptic Ulcer.**—Chamberlin and Perkin estimated the ascorbic acid in the blood of twenty-seven hospitalized patients with peptic ulcer. Lower levels of ascorbic acid were found in the blood and urine of these patients than in normal individuals or patients with functional digestive disorders. That patients with peptic ulcer require a greater

amount of ascorbic acid is demonstrated by the fact that daily medication with ascorbic acid results in an earlier and greater excretion of ascorbic acid in the urine of normal individuals and patients on other dietary management than in patients with peptic ulcer. The amount of additional ascorbic acid required to raise the excretion of ascorbic acid to normal in patients with peptic ulcer appears to be 50 mg. four times a day. It is suggested that the metabolism of ascorbic acid is influenced by activity and that lower blood and urine values are found in patients resting in bed than in active persons.

**Cervical Rib in Early Life.**—Davis and King state that in the latter half of 1936 three children with cervical rib were seen at the John Gaston Hospital and at the outpatient clinic. This succession of cases suggested that similar cases might previously have been overlooked. Therefore 1,000 consecutive roentgenograms of the chests of children less than 13 years of age were studied. The incidence of cervical rib in the 1,000 consecutive roentgenograms was 1.2 per cent. Reproductions of the roentgenograms in the twelve cases are depicted. Ten of the cases were bilateral and the two unilateral ones were affected on the left. Only two were in male children. Every patient with cervical rib had a long neck and a hyposthenic thorax. A marked variation was noted in the size and contour of the anterior root of the transverse process of the seventh cervical vertebra. In many instances it reached such proportions that it was difficult to differentiate it from a rudimentary cervical rib. This may be explained by the developmental anatomy of the seventh cervical vertebra. The diagnosis of cervical rib will be made more frequently if the symptom complex is borne in mind. Oblique roentgenograms of the neck and the upper part of the chest taken with the rays directed upward, laterally and posteriorly through the seventh cervical vertebra will demonstrate more clearly the actual proportions of the rib. In the interpretation of roentgenograms of children less than 5 years of age, the presence of a separate piece of bone adjacent to the transverse process of the seventh cervical vertebra should be recognized as a center of ossification which is a potential precursor of a cervical rib.

**Poliomyelitis Following Tonsillectomy.**—Stillerman and Fischer studied the 686 patients with poliomyelitis who were admitted to the Willard Parker Hospital during 1935 in order to determine whether the removal of the tonsils and adenoids in any way influenced the onset or clinical type of the disease. It was found that tonsillectomy and adenoidectomy had been performed in ten cases during the month antedating the illness. In eight of these poliomyelitis began from ten to twelve days and in the other two sixteen and twenty-two days, respectively, after the operation. Six of the ten patients had the bulbar or encephalic form of the disease. Careful inquiry

was made among the fifty-two patients with poliomyelitis that were admitted to the hospital during 1937. In three of these patients tonsillectomy had been performed from two to three weeks preceding the onset of poliomyelitis. These three children had the bulbar type of disease. All of them died. The bulbar or encephalitic type of poliomyelitis was present in sixty-eight of the 686 patients and in fifteen of the fifty-two patients, while in six and three patients respectively who recently had their tonsils and adenoids removed the bulbar or encephalitic type developed. Thus there was a disproportionately high percentage of bulbar involvement in the tonsillectomized patients in both the 1935 and the 1937 outbreak. This much higher incidence of bulbo-encephalitic forms suggests the operative field as the port of entry of the virus. They conclude, therefore, that tonsillectomy and adenoidectomy should not be encouraged during an epidemic of poliomyelitis.

Zosteriform Lichen Planus. M. I. Davis, Nashville, Tenn.—p. 615.

**Liquefying Nodular Panniculitis.**—Shaffer presents a case of nodules in the subcutaneous fatty tissue, associated with fever. The essential clinical features are that (1) deep-seated, painful and tender, woody nodules appeared in the subcutaneous fatty tissue, (2) they evolved in from seven to ten days into cystic masses containing from 1 to 4 ounces (30 to 120 cc.) of an oily or fatty yellowish brown fluid, (3) just before rupture (from ten to fourteen days) the skin overlying the mass was livid and raised while the central portion was attenuated into a thin translucent bulla-like membrane, (4) a deep cuplike depression formed in the subcutaneous fat, associated with a thin puckered scar, at the site of the healed lesion, (5) fever was present when the active lesions were most numerous and (6) the lesions occurred on the buttocks and extremities. The histologic features of the process are a primary round cell infiltration, the disappearance of the fat cells and their replacement by foam cells and the eventual liquefaction of the process.

### Treatment of Herpes Simplex with Moccasin Venom.

—Kelly treated fifteen cases of herpes simplex and three of herpes zoster with moccasin venom in a 1:3,000 dilution. The venom was given intradermally in doses of 0.2 cc. Since the disease is usually of short duration, an attempt was made to treat it only in the incipient stage, i. e. when itching, burning, swelling and slight vesiculation were present. In twelve cases of herpes simplex in which treatment was begun early, i. e. within eight to twenty-four hours after onset, the subjective symptoms disappeared within five to twelve hours after the snake venom was injected and the swelling and vesiculation disappeared within twelve to thirty-six hours, the vesicles being replaced by small dry crusts with no exudation. In the three other cases, in which the eruption had been present for longer than twenty-four hours, the duration and course of the disease were unaltered, although the patients stated that the subjective symptoms were noticeably lessened. The course of the disease in the three cases of herpes zoster appeared to be unaltered. However, the patients, each of whom had complained of severe burning and itching when first seen during the stage of vesiculation, stated that the subjective symptoms were alleviated.

**Treatment of Myoma Uteri.**—Lee states that of the last 3,000 cases admitted to the gynecologic service of the Cooper Hospital 500 have been cases of fibromyoma. Myomectomy was performed in twenty. This is the preferred method of treatment whenever possible. It has been most useful in pregnancy complicated by fibroid. Myomectomy should always be done in submucous fibroids in the nonpregnant young patients. The author considers extensive adnexitis, very large tumors and nearness to the approaching menopause contraindications to myomectomy. When indicated, the morbidity and mortality of myomectomy are negligible. Subtotal hysterectomy was performed in 385 cases. The mortality and morbidity of subtotal hysterectomy are low owing to the fact that the technic has been simplified and standardized in recent years. Total hysterectomy was done in five cases. The total operation is done when malignant manifestations in the cervix are suspected. In other cases the cervix, after receiving proper treatment, may safely remain. Amputation, tracheloplasty or the cautery may be used to accomplish this purpose, although tracheloplasty is preferred in the average case. In selected cases vaginal hysterectomy is undoubtedly a procedure of choice, with a low mortality and most gratifying convalescence. Its use should be restricted to those cases in which there has been no history of severe pelvic infections and in which neither the uterus nor the adnexa appear fixed by adhesions. Total vaginal hysterectomy is indicated for very stout persons, for old persons with a small tumor, for patients who have no history of severe pelvic inflammation, in procidentia when removal of the uterus is desirable and in suspicious conditions of the cervix with fibromyoma with a roomy pelvis. Vaginal hysterectomy for the removal of large fibroids is to be deplored. When radium is used the tumor should not be larger than a three months pregnancy, it

should not be pedunculated, there should be no pressure-symptoms on the bladder or the intestine, there should be no history of recent pelvic inflammation and the patient should be at or near the menopause or older. Radium was used in fifty-four cases of the present series. The symptom for which radium has been used is uterine bleeding and no reirradiation has been necessary. The reduction in the size of the tumor averages about one third and requires about one year to be complete. X-ray irradiation has little place in the treatment of fibroids. It should be reserved for inoperable cases, cardiac or otherwise and in some tumors too large for radium. Small fibroids which do not give rise to symptoms should be left alone. Many of these grow slowly and never attain sufficient size to menace the patient's health. They practically all tend to retrogress at the menopause. A malignant growth in the fundus was encountered in four of the 500 patients. Five patients died, one each from hemorrhage, septicemia, coronary thrombosis, peritonitis (complicating cancer of the rectum) and diabetes.

**Dyspnea in Anthracosilicosis.**—Charr and Savacool determined the vital capacity, venous pressure and pulmonary circulation in twenty cases of pure anthracosilicosis and for comparison twenty cases of tuberculosis in which there was marked collapse of one lung under artificial pneumothorax or thoracoplasty. They found that dyspnea in anthracosilicosis is not always directly proportional to the reduction of the vital capacity while it is to the length of the pulmonary circulation time. In fact it appears that this dyspnea is largely due to cardiac insufficiency. Myocardial degeneration is a common observation in anthracosilicosis and is due to pulmonary fibrosis, emphysema and pulmonary arteriosclerosis, which are almost always present. When an anthracosilicotic patient is studied for compensation, possible myocardial insufficiency as well as the pulmonary damage should be determined. For such study the estimation of the velocity of the pulmonary circulation may give aid.

**Prolonged Use of Sulfanilamide.**—Alpert and Forbes contend that severe streptococcal and meningococcal infections, such as otitis, cervical adenitis, sinusitis, mastoiditis and involvement of the meninges, demand intensive and prolonged administration of sulfanilamide if relapses are to be obviated. In a series of 200 children given sulfanilamide therapy by one of the authors relapses occurred in approximately 7 per cent. Otitis and cervical adenitis were the most frequent complications tending to relapse and required prolonged administration of sulfanilamide. Impetigo contagiosa yields promptly to sulfanilamide, but relapses are not infrequent following courses of from three to five days of the drug. Severe toxic effects of sulfanilamide can be avoided if the leukocyte count, the hemoglobin percentage and the concentration of sulfanilamide in the blood are determined daily for patients receiving large doses of the drug. The rationale for continuous treatment can be found in the mode of action of the drug. It is now generally agreed that the action of sulfanilamide is mainly that of bacteriostasis and not that of a bactericide.

**Encephalomyelitis Complicating Virus Infections.**—Lancaster reports seven cases of encephalomyelitis in which the etiologic factor is considered to be a filtrable virus. Three followed chickenpox, two measles, one vaccination and one mumps. Encephalomyelitis complicating any of the virus infections may show a wide variation in symptoms, but in chickenpox the particular points that stand out are (1) the infrequency of headache as a symptom, (2) a marked tendency to cerebellar disturbance and (3) favorable prognosis, both as to life and as to the absence of sequelae. Since there is a definite associa-

tion between vaccination and the consequent encephalomyelitis there can be little doubt that vaccination is etiologic, although such complications are rare. In most cases the period elapsing between the time of vaccination and the onset of nervous symptoms is fairly constant (ten days). Sequelae have been rare: the principal distinguishing point between this condition and epidemic encephalitis. In measles the prominent features are (1) the greater tendency to polymorphism of symptoms and (2) the extremely high percentage of cases showing definite and permanent damage to the nervous system. In measles as well as in the other conditions the severity of the primary illness is not a determining factor in the occurrence of complications or the severity of the complications when they appear. In mumps probably the most common complication is that of meningeal irritation, and the symptoms follow closely those of true meningitis. In the case reported the noteworthy feature was the myelitis, which comes under the rarer forms of neurologic complications in this disease. The prognosis is favorable with an exceptionally low mortality and a tendency to a complete recovery and in those cases showing only meningeal symptoms the course of the illness is brief.

**Blood Supply and Calcification of Bone.**—Blair states that disuse is known to produce rarefaction and bone atrophy. This rarefaction is due to the absorption of the mineral elements of bone. The cellular constituents remain and as activity is resumed the complicated bone salt is replaced. Activity is due to one thing only—the contraction and relaxation of muscles controlling the extremity involved. Ischemia, even slight, will produce a localized acidosis in the pressure area. The change toward the acid reaction and toward the alkaline side appears to be accomplished quickly and by very little change in the blood supply. By the contraction and relaxation of muscles it would seem that these changes could be brought about in bone. It does not seem possible that reossification of bone is produced in any other way; weight bearing and stress and strain can be ruled out because even the slight activity of a person confined in bed will prevent the atrophy of the bone or bones of a limb not encased in plaster. Alternating ischemia and hyperemia can

produce a comparative alternation in the hydrogen ion content of tissue fluids. It is assumed that during a rest period when muscles are relaxed, particularly just after exercise, when arterial flow is markedly increased, a swing toward the alkali side is taking place. Phosphatase acts best in hydrolysis of the phosphoric ester in an alkaline medium. At this period inorganic phosphates should increase in the tissue fluids. Muscular contraction taking place produces an ischemia, a lower hydrogen ion concentration, and as a more acid reaction develops more calcium is ionized and the tissue fluids are able to hold in solution a higher supersaturation of calcium. As muscular relaxation takes place and the swing is again toward a higher hydrogen ion concentration, the law governing salts that are soluble with difficulty causes a precipitation of the complex bone salt, composed of calcium carbonate and calcium phosphate. Theoretically it would seem that the clinical use of alternating suction and pressure, by increasing and diminishing the blood supply to the part by contraction and relaxation of the muscles, might aid in the production of union.

**Treatment of Intractable Pruritus Ani.**—Manheim and Druckerman excised completely all the diseased tissues in three cases of severe and intractable pruritus ani accompanied by advanced cutaneous changes. The operation is as follows: The sphincter is gently dilated, not divulsed. The entire affected area is circumscribed by a circular incision, which usually is at a radial distance of from 2 to 3 inches from the anal margin. The incision is carried down through the entire thickness of the skin until normal subcutaneous fat is encountered. The dissection is then continued in the subcutaneous tissue up to the mucocutaneous junction. The fibers of the corrugator cutis ani muscles are severed, and the subcutaneous portion of the external sphincter muscle is carefully exposed and protected. The cone shaped area of the skin is then split anteriorly and posteriorly in order to facilitate the subsequent section at the mucocutaneous junction, which is performed after clamps are placed on the mucous membrane to prevent retraction. The gluteal skin is mobilized for a distance of from 1 to 2 inches. All bleeding points are carefully controlled. Four silk mattress sutures are placed between the mucous membrane and the cutaneous edges at equidistant points anteriorly, posteriorly and laterally. Interrupted silk sutures are used to complete the approximation. A small piece of petrolatum gauze is inserted into the newly constructed anal canal and the entire operative area is covered with it. The results were gratifying. Pruritus disappeared immediately after operation. Surprisingly little pain was present throughout the convalescence. Complete healing occurred in from six to ten weeks. All three patients have been completely relieved and have remained so for from four to twenty-two months after operation. The method is not recommended for the treatment of the usual case of pruritus ani but only for long standing, intractable pruritus ani, particularly when accompanied by pronounced and possibly premalignant cutaneous changes.

**Bacteriophage in Dysentery.**—Haler discusses an outbreak of dysentery in an institution for blind children (population thirty-two) from a few months to 7 years of age. The first patient became ill Feb. 20, 1937. The only important symptom was a little blood in the stools. This child was not suspected of having dysentery and after being segregated for a few days was allowed to join the other children freely. The epidemic followed six weeks later, but April 22 the same child was ill again. On the latter occasion the first stool to be examined showed no dysentery bacilli, but April 25 *Bacillus dysenteriae* Sonne was obtained. Following this presumed first case of February 20 there were three cases on April 4 and 5, four more cases April 10 and 11, another febrile case of dysentery occurred April 18, and April 22 the first patient was again reported ill. It is possible that this patient may have harbored *Bacillus sonnei* from February 20 and thus have been the source of the other infections. April 25, three more cases occurred. Bacteriophage treatment was recommended for those who had been sick, those unaffected and all the staff. All those in bed and on bed isolation received dysentery bacteriophage three times daily until the stools were reported "free from *Bacillus dysenteriae* Sonne and from atypical dysentery bacilli." On the second day after treatment was begun, one further case occurred. This was the last; and now, more than a year later, there has been no fresh case. This sudden cessation of the epidemic may have been a coincidence, but there was nothing to suggest that the cases between April 4 and 27 were being infected from outside the home. The repeated isolation of *Bacillus dysenteriae* Sonne from the stools suggested that this infection was being spread. No medicinal treatment other than bacteriophage was administered.

**Salmonella in Milk and Butter.**—The experimental results of Pullinger and Kemp show that the *Salmonella* which is likely to contaminate milk supplies and which causes either typhoid or food poisoning in man grows readily in freshly drawn milk stored under normal commercial or household conditions when refrigeration is not resorted to. Any effect exerted by the growth-inhibitory factor of fresh milk is transient, since multiplication was observed even after small initial inoculums had been added to the milk. The inhibitory factor was not bactericidal for *Salmonella*. Whether contamination originates

from the cow, as usually happens with *Salmonella dublin*, or from some external source as with *Salmonella typhi*, the really important factor in the epidemiology of milk borne *Salmonella* outbreaks is that the contaminating organism can thrive during storage and thus cause wholesale contamination of pooled milk. A point of some interest which has arisen out of the investigation is the fact that strains of *Salmonella typhi* recently isolated from human cases multiplied more rapidly in milk than did old laboratory stock cultures. When artificially incorporated in butter after manufacture, these organisms were found to survive for periods varying from two to three months and even longer when the butter was stored at 15 or 3 C. Neither the quality of the butter nor the presence or absence of salt appeared to influence this survival. There was no suggestion that any multiplication occurred, and after about two months' storage the organisms began to decrease in numbers.

Carcinoma of the Tongue: Late Results of Treatment. R. Phillips.—p. 772.  
Osteomalacia of Spine Following Abuse of Laxatives. E. Meulengracht.—p. 774.

**Air Embolism.**—Osborn and Dawson report three cases of air embolism: two complicating labor at full term free from infection (in each the postmortem examination was made before decomposition could complicate the observations) and one of a boy aged 16. None had been treated with chemicals. At necropsy both women showed definite fatty changes in the liver, a condition often found in unexpected deaths. In the first case the severity of this change may have been the reason for the extraordinary atonicity of the uterine muscle. The histories of the two women from the time the air presumably gained access to the veins is strikingly similar and the times taken to die (three and one and one-half hours) are noteworthy. The liver and alimentary tract in the third case appeared normal. The kidneys showed a severe chronic nephritis which was evidently responsible for the cardiac hypertrophy. The renal pelvis and ureters were normal. The bladder was empty; there was a hemorrhage of about 60 cc. into the tissues to the left of it, which was not connected with the much larger hemorrhage into the mediastinal tissues. There was no tear of the bladder or injury of the rectum. According to the mother, the boy seemed all right when he got out of bed to pass urine, so that much of the blood present in the pleural cavity was probably the result of postmortem bleeding. Air embolism presents characteristic symptoms. These are sudden onset, disappearance of the pulse, deep respirations with air hunger, restlessness with chest discomfort (shown especially by lashing about with the arms) pallor if the case is immediately fatal, associated with fright and cyanosis if death is delayed. If the condition should be recognized during life it is conceivable that aspiration of the right side of the heart would avert a fatal issue.

**Journal de Médecine de Lyon**

19: 527-554 (Sept. 20) 1938

\*Etiology of Angina Pectoris. L. Gallavardin.—p. 527.

**Etiology of Angina Pectoris.**—The anginal syndromes which are the object of this study by Gallavardin are those of true angina of coronary origin. This statistical report, which is based on approximately 1,900 cases, reveals that angina pectoris is much more frequent in men than in women, the ratio being about 4:1. The onset of the anginal symptoms is most frequent in persons between the ages of 45 and 65 years; that is, in nearly 75 per cent of the cases the onset occurs during those years. The role of syphilis is important but limited and the author thinks that formerly the significance of syphilis in angina pectoris was greatly exaggerated. The proportion of syphilitic patients (certain and doubtful cases) does not exceed 20 per cent of the total number of patients with angina pectoris. However, the influence of this infection is the more evident, the younger the patients are; it plays a part in not far from 50 per cent of those under 35, in nearly 40 per cent of those under 40 and in nearly 25 per cent of those under 50. In those above the age of 50 the incidence decreases rapidly to from 15 to 18 per cent for men and to from 5 to 8 per cent for women. The author says that nicotine is not the only cause of nonsyphilitic angina pectoris. Of the men with nonsyphilitic angina pectoris, more than 20 per cent had never smoked; if the women are included, the percentage of nonsmokers exceeds 40. Coronary angina pectoris by itself has nothing in common with arterial hypertension. In the author's material more than 60 per cent of the men had a tension which did not exceed 160 mm. of mercury. However, the coexistence of the two disorders is quite common in women as well as in men. It is even possible that certain hypertensive states provoke, especially in women, the appearance of an anginal syndrome which does not depend on coronary lesions.

46: 1449-1464 (Oct. 1) 1938

\*Buccal Cacosmias. G. Sanarelli.—p. 1449.

Hemorrhagic Rectitis. P. Oury and R. Stieffel.—p. 1452.

**Buccal Cacosmias.**—Sanarelli says that halitosis, or buccal cacosmia, has nothing in common with the enteropulmonary gaseous exchange, by which the odors of certain ingested substances may be temporarily noticeable in the expired air. Buccal cacosmia is not a transitory condition but a permanent disorder, which frequently exerts a harmful influence on the psyche of the patient. Medical science has ascribed it to banal causes such as digestive irregularities or poor condition of the teeth. The buccal cacosmia with which the author is concerned in this report is of the "essential" type, which should not be confused with the halitosis of persons who have acute or chronic inflammatory processes with a pulmonary or buccopharyngeal localization such as pulmonary abscess, bronchiectasis, sinusitis, mercurial stomatitis, chronic tonsillitis or dental pyorrhea. He applies the term essential buccal cacosmia to the permanent halitosis in persons who otherwise appear healthy. Reviewing the hypotheses on the origin and nature of essential buccal cacosmia, he mentions those of Boldyreff and of Tamches. He directs attention to the antimicrobial action of saliva, which he demonstrated as early as 1892 and which was confirmed by other investigators. Further he describes his more recent studies on the bacterial flora, directing especial attention to the antiputrefactive action of the buccal streptococci. After describing several of his experiments on the bacterial origin of essential buccal cacosmia, he says that the results are always the same; that is, the buccal streptococci in the presence of even small quantities of carbohydrates succeed always by means of their acidifying diastases to impede the development (in the buccal cavity as well as in vitro) of other species of micro-organisms, including the putrefactive ones. If carbohydrates are lacking, the bacteria of putrefaction become predominant and in the presence of proteinic substances give rise to fetid odors. In the further discussion the author points out that, owing to the mild antimicrobial action

of the saliva, the continuous salivary irrigation of the buccal mucosa tends to reduce the abundant development of the oral bacterial flora. However, if the buccal or intestinal secretions undergo changes, the conditions become favorable for a free and abundant development of the bacterial flora. The author thinks that this is the reason why patients with disturbances of the digestive tract, who lack appetite and are nauseated, often have a fetid breath. These are the pathologic conditions of the stomach which exercise an indirect influence on the buccal mucosa and consequently on the salivary secretions. In the conclusion the author emphasizes once more that the origin of buccal cacosmia is not gastric, intestinal, pulmonary or due to particular microbes giving off the fetid odors. It is entirely local, being caused by banal putrefactive fermentations, which manifest themselves in the buccal cavity under the aforementioned abnormal local or general conditions.

\*Clinical and Biologic Study of Pleural Effusion in Patients with Cirrhosis. M. Goffart.—p. 341.

Physicochemical Modifications of Blood After Surgical Interventions Under Various Anesthetics. I. Blitstein.—p. 371.

**Pleural Effusion in Patients with Cirrhosis.**—Goffart reviews the clinical histories of ten cases of pleural effusion in cirrhosis and then gives his attention to the pathogenesis. In conclusion he states that the pleural effusions are frequent in patients with cirrhosis. The appearance and evolution of pleural effusion is hardly noticeable and it must be searched for carefully in the course of the examination. The physical signs are deceiving, the roentgenologic examination underestimates the quantity of liquid and an exploratory puncture is necessary to settle the doubt. The pleural effusion does not aggravate the prognosis, except for septic complications. The effused fluid is relatively poor in albumin, fibrin and cholesterol. Its cytology is mixed; it always contains blood and the chloride content is increased. The pathogenesis is complex and it is unquestionably justifiable to invoke the mechanical causes of pulmonary stasis by elevation of the diaphragm; the reduction of the osmotic power of the proteins by inversion of the albumin/globulin ratio of the serum, and the impaired functional activity of the capillaries. The author says further that tuberculosis must still be regarded as a possible causal factor of pleurisy, but he did not detect it as a cause in the cases which he observed.

\*Experimental Transmission of Poliomyelitis to Cattle. E. Frauchiger and W. Hofmann.—p. 1140.

**Experimental Transmission of Poliomyelitis to Cattle.**—Frauchiger and Hofmann cite Frauchiger's report about a case of spontaneous poliomyelitis in a heifer (THE JOURNAL, July 2, 1938, p. 74). This observation induced them to attempt the transmission of poliomyelitis to cattle, although it was generally believed that monkeys were the only animals that could be inoculated with this disease. Poliomyelitis material from human subjects (brain and spinal cord) was inoculated into three heifers aged between 12 and 18 months. Since it was the first aim to determine whether the inoculation would take, large doses were given and the material was introduced by three different routes (intranasal, intraperitoneal and intraspinal). Only one of the animals was not subjected to the intraspinal administration. Besides increases in temperature at the onset, there were no general symptoms such as gastrointestinal disturbances, nasal discharge and sweating. Moreover, there were no signs of meningeal irritation (stiffness of the back). However, after two or three days signs of paralysis appeared on the extremities, particularly the posterior ones. The paralytic symptoms increased to the seventh day. In one of the animals they persisted in about the same intensity, whereas in another one they disappeared, but never completely.

During the severest stage of the disease the animals had an atactic walk and frequently fell down. Completely flaccid paralysis was not observed. The third animal, which had not been subjected to intraspinal inoculation, showed a mild paresis which soon disappeared again. The walk and the behavior of the animals were recorded on a kinematographic film. In the fourth week after the inoculation, bilateral atrophy of the gluteal musculature was observed in one of the animals. In another animal atrophies were observed in the musculature of the pelvis and thighs as well as on the right foreleg. Examination of the cerebrospinal fluid of the animals revealed changes indicative of organic disease of the central nervous system, but since microscopic studies have not been made as yet the authors are unable to state whether the disease process is identical with that of poliomyelitis. However, further investigations will be devoted to such microscopic studies and to attempts to transmit the disease further by means of material obtained from these animals.

#### **Treatment of Thrombosis and Thrombophlebitis.**

Pardella reports satisfactory results of hirudinization (local application of leeches) and application of a bandage of wide adhesive tape in twelve cases of puerperal and postoperative thrombosis and thrombophlebitis of the legs. The leg is raised to about 40 degrees for a few minutes, during which the joints of the ankle and knee are covered with a thin layer of cotton and the bandage is applied from the distal end of the middle third of the foot up to a point near the root of the thigh. Compression and tension of the bandage are moderate and uniform. The toes are not included in the bandage, which is applied in such a manner that the lower half of each new turn of the adhesive tape covers the upper half of the turn previously applied. Immediately after application of the bandage, the patient is asked to perform a few slight movements of flexion and extension and the limb is placed at rest. Four or six leeches are placed at the anterolateral aspect of the thigh near its root. They are changed two or three times at intervals of twenty-four hours in septic thrombophlebitis and discontinued after the first application of twenty-four hours in simple thrombosis. A few moments are spent in flexion and extension on the sixth and ninth days of application of the bandage. According to the author the immobilization of the local venous system induced by the bandage results in normalization of the local venous and lymphatic circulations with consequent reabsorption of edema, improvement of the nutritional conditions of the tissues and rapid control of the disease. The patients are relieved from the first day. The treatment lasts for from nine to thirteen days, according to the evolution of edema, pain and the general symptoms. The satisfactory results are permanent, as verified by the author through further observation of the patients.

**Pain After Appendectomy.**—Pieri states that in the course of the last five years thirty-six patients have complained to him of persistent pain in the right iliac fossa after an appendectomy for either chronic or acute appendicitis. In the majority of the cases the pain began several hours after meals. The

roentgen study of the cecal region failed to show any pathologic changes of the cecum. A right vertical laparotomy showed that in four cases pain was caused by the presence of post-operative adhesions, removal of which induced recovery of the patients. In thirty-two cases one of various pathologic conditions (chronic colitis, simple, tuberculous or acute typhilitis or ileotyphlitis, mobile or atonic cecum and cecal neuralgia) existed. Resection of a segment of 2 or 3 cc. of the ileocolic plexus between two ligatures and through a right vertical laparotomy induced recovery of the patients, which was verified by a follow-up observation. In Italy the operation is known by the author's name, since he is the originator. Permanent satisfactory results have been reported from several Italian hospitals.

#### **Acquired Posterior Sinistocardia.**

Giordano describes a rare form of tuberculous fibrothorax with permanent lateral posterior displacement of the mediastinum and mediastinal organs, especially the heart and large blood vessels. In the roentgenograms of the thorax which are taken in the latero-lateral position, the cardiovascular shadow shows at the paravertebral region separated from the sternal wall by lung tissue. The author reports four new cases. All the patients were adults suffering from pulmonary tuberculosis with fibrothorax, which developed spontaneously or after artificial pneumothorax or a surgical operation in pleural empyema. Stabilization of fibrothorax and subsequent transposition of the heart to the left had taken place in all cases during either youth or childhood. All had acute bronchiectasia. Bronchography showed that the lower and middle lobes of the lung were emphysematous and displaced to the left, between the sternal wall anteriorly and the cardiovascular shadow posteriorly. The esophagus, especially the thoracic segment, was dilated and retracted to the back in two cases and to the left in two cases. There was no stricture of the esophagus. The trachea, its bifurcation and the left bronchi were displaced to the left and greatly dilated and deformed in two cases, in one of them to a large extent. The author advises further study of the subject in order to determine the mechanism of production of the special displacement of the mediastinum and mediastinal organs in this form of tuberculous fibrothorax.

#### **Influence of Succinic Acid on Diabetic Ketosis.**

Müller and Buchwald state that the literature contains contradictory reports about the effect of succinic acid on diabetic ketosis and so they decided to investigate this problem on a considerable number of their patients. In doing this they not only determined the elimination of ketone bodies in the urine but also examined the ketone content of the blood several times each day. Summarizing their observations, they state that the clinical examination of the succinic acid therapy of diabetic ketosis, which was recommended by Koranyi and Szent-Györgyi, revealed that the oral administration of succinic acid, even if continued for weeks, does not compensate a diabetic acetonuria. They did not even observe a temporary reduction in the daily ketonemic curve.

Moreover, the typical ketonemic curve observed in diabetic patients, after they have been subjected to a fat tolerance test, could not be influenced in the antiketogenic direction by the administration of succinic acid.

**Relations Between Varicella and Herpes Zoster.**—Hourand reports the clinical history of a woman aged 50. He regards this case as important in connection with the problem of the relation between varicella and herpes zoster. The woman developed herpes zoster with the typical symptoms: strictly localized vesicles of various sizes, reddishness and swelling of the skin with great painfulness; the left eye was involved. This attack of herpes zoster was followed a few days later by varicella. The author reviews the literature on the relation between varicella and herpes zoster, citing the concurrence of these two disorders in the same cases but also the development of varicella in persons who had come in contact with persons having herpes zoster and vice versa. After mentioning serologic and immunologic investigations on the etiologic relation between the two disorders, he says that several authors reject the identity of the viruses of varicella and herpes zoster. Some cite the successive appearance of varicella and herpes zoster after intervals of several months as evidence against such an identity but others believe that in such cases the causal agent of varicella, as a dermatotropic virus, confers immunity only on the skin, whereas the neurotropic virus of herpes zoster confers immunity only on the nerves. However, this partial immunization is regarded as the exception and the general immunization as the rule. Returning to the reported case, in which herpes zoster and varicella concurred, the author says that dermatologists have referred to these cases as herpes zoster generalisatus. However, he agrees with von Bokay, Netter, Haslung and others, who reject this term, because in his patient the vesicles were not arranged along the course of certain nerves.

\*Care for Soft Parts During Delivery by Practitioner. J. Baart de la Faille.—p. 4315.

**Care for Soft Parts During Delivery.**—Baart de la Faille assumes an antagonism between the uterus and the soft parts during delivery. The violent pain of the period of dilatation is only partly the result of the uterine contractions. Anxiety and cold cause an extremely painful spasm and this inhibits the labor pains and the dilatation of the os, real rigidity of the os being extremely rare. By adequate heating of the bed and the room, much pain can be saved; the same applies to the use of antispasmodics and analgesics. The author found that with the increasing variety of these drugs the uterine action can be utilized to full advantage, weakness of uterine contractions occurring far less and solution of posterior pituitary being only rarely required. The first stage of labor, the period of dilatation, can be shortened in a considerable percentage. The uterine contractions during expulsion, although less painful, likewise are acted on favorably by these medications, the difficulties of expulsion becoming far less if nature is left to have its own way. The process of distending the soft part thus becomes much more gradual and the indication for extraction by forceps becomes much less frequent. Among the results of excessive distention the author differentiates prolapse from rupture, the former ensuing after forcible distention of the pelvic diaphragm, the latter being limited to the perineum. Slow distention of the pelvic diaphragm pre-

vents a prolapse and slow dilation of the vulval ring reduces the danger of a rupture and the necessity of a suture. The author is skeptical of the value of suturing the perineum. However, he emphasizes that lifting of heavy objects should be avoided for six weeks after delivery.

Porphyries and Clinically Applicable Methods for Their Establishment. A. Eldahl.—p. 864.

\*Symptomatology of Acute Porphyria and Classification of Porphyrias. A. Eldahl.—p. 871.

Essential Fibrogenic Hemorrhagic Diathesis. N. I. Nissen.—p. 879.

**Acute Porphyria and Porphyrias.**—Eldahl says that acute porphyria is a well defined disorder of acute onset, the main symptoms of which may be violent abdominal pain, constipation (in rare cases diarrhea), organic disorder of the cerebrum and medulla (insomnia, psychosis, multiple pareses), hepatic and renal insufficiency and elimination of porphyrin and chromogen in the urine. The symptoms of disorder of the cerebrum and medulla especially mark the disease and resemble those in encephalitis and poliomyelitis. Acute porphyria is ascribed to a congenital and hereditary anomaly in the intermediary metabolism, a latent or relative insufficiency of the porphyrin synthesis, which can often become absolute. The synthesis probably takes place in the liver. The immediate cause may be infections, often mild infections, overexertion, psychic attack or chemical substances in small amounts. The prognosis is unfavorable; the mortality is about 70 per cent. About 70 per cent of the patients are women, mostly between the ages of 20 and 30; no case under the age of 15 has been reported. Patients with porphyria are often dark skinned but without hypersensitivity to light. Anatomopathologic examinations show slight cirrhotic changes in the liver, in some cases hemosiderin deposits, acute nephritic changes in the tubuli contorti of the kidneys and interstitial leukocyte accumulations, signs of obliterating phlebitis in the kidneys and other organs, and in some cases slight hemorrhages in the cerebrum. In many cases diet treatment has been given such as was formerly generally applied in hepatic and renal disturbances; in the author's personal case of acute porphyria, which originated during hospitalization, insulin and dextrose was administered. Porphyrias are classified in two groups: (1) without symptoms, (a) familial hereditary, constant or periodic, (b) symptomatic, in fever, anemia and so on, (c) medicamentous, after arsenamine and sleeping powders; (2) with symptoms, (a) in porphyria, (b) toxic, after arsenic, lead, sleeping powders and so on, (c) in hydroa vacciniforme.

Paroxysmal Myoplegia: Case. J. E. Poulsen.—p. 998.

Plummer-Vinson's Syndrome: Case. H. Videbech.—p. 1001.

**Epidemic Alveolopneumonia and Psittacosis.**—Rasmussen concludes from the account of the sixty-eight cases of primary epidemic alveolopneumonia observed in the Faroe Islands in September, 1933 (Arthur A. Rasmussen, *Ugeskrift for læger*, 1934) that the disease is clinically like psittacosis and has much in common with it epidemiologically. The two diseases affect the same age group and cause about the same mortality. However, while psittacosis is a disease of fall and winter, primary epidemic alveolopneumonia occurs almost exclusively in the month of September and affects six times as many women as men, and particularly pregnant women. The incubation period is unknown. The agreement between the time of the catch of the young procellarians (storm birds) and of the incidence of primary epidemic alveolopneumonia suggests that the source of infection may be in these birds, in which case the infection must be transmitted in the plucking and cleaning of the birds. The author also calls attention to the resemblance of this disease to other disorders, such as streptococcal pneumonia and streptococcal sepsis, and in its milder form to the initial fever of tuberculosis.

## SPONDYLOLISTHESIS AS AN ETIOLOGIC FACTOR IN BACKACHE

HENRY W. MEYERDING, M.D.

ROCHESTER, MINN.

Spondylolisthesis may be defined as subluxation of a vertebra, usually forward, and most commonly in the lumbosacral region, where it may produce narrowing of the pelvis. Backache is its most common symptom and forward and downward displacement of the lumbar spine its most common deformity. Recognized in 1853 by Killian as a clinical entity, spondylolisthesis was considered a rare condition and one that most commonly affected women. I am convinced that this deformity has escaped the attention of the general profession and that it will become an increasing factor in solving the problem of the relief of chronic backache.

In my experience males are afflicted in the majority of cases, which is contrary to the earlier teachings. I believe that trauma and congenital defects are the important etiologic factors in spondylolisthesis and that obesity, occupational strain and pregnancy may aggravate or produce the symptoms and increase the deformity. Old injuries, sustained months or years previously, may be the (unrecognized) factors which have produced the subluxation, but the most important factors are congenital anomalies which result in weakness in the lumbosacral region.

General practitioners are often called on to fix responsibility for, and to estimate the duration and degree of, such disability. On relief of symptoms they are in a position to return the patient to his occupation and to adjust a fair rate of compensation. In venturing an opinion in cases in which compensation is sought for disability due to chronic backache following overlifting or back injuries, and in cases in which malingering must be considered, I would remind them of the following statement I made before the American Orthopaedic Association in 1931: Pain in the lower part of the back, which is relieved by rest, aggravated by work and associated with industrial injury, suggests the possibility of "railroad spine," traumatic neurosis, and so on, yet these disorders are commonly complained of by patients with spondylolisthesis whose appearance is often apparently normal and who seem to be enjoying undeserved benefits. While in my experience in the neighborhood of only 7 per cent of such cases have been diagnosed previously, present knowledge of the deformity makes it possible for the physician to recognize it,

ascribe responsibility to the factors involved in its production and relieve the symptoms to a larger extent.

Time and space cannot be given in this paper to a complete review of the literature. Killian, as has been said, first recognized the deformity and believed that it resulted from caries and inflammation. In 1866 Blake reported the first case in the United States, that of a multipara who had gained 100 pounds (45 Kg.). Neugebauer in 1844 studied museum specimens and, although he recognized congenital defects, believed trauma to be the principal etiologic factor. In 1897 Lovett described the first case of traumatic spondylolisthesis; his and Gibney's patient (both males) were included in the first six males in a series of 125 patients whose cases had been recorded in the literature up to 1900. Asbury reported on spondylolisthesis in 1927 and felt that it was a definite factor in the production of backache.

The apparent rarity of spondylolisthesis is due to failure on the part of the average examining physician to recognize the deformity. In 1920, for example, only one diagnosis was made of spondylolisthesis at the Mayo Clinic. The number of diagnoses of spondylolisthesis has increased *pari passu* with the increase in our clinical and roentgenologic skill and experience. In 1937 alone eighty-one cases were recognized at the clinic. During the preparation of this paper I saw three patients with spondylolisthesis in a single day.

The subluxation is frequently recognized from inspection of the back alone (fig. 1); the location and grade of the deformity and the type of congenital defect present are determined from examination of lateral and anteroposterior roentgenograms.

I have reviewed a series of 583 cases of spondylolisthesis seen at the clinic and am presenting an exhibit, consisting of roentgenograms and models, at this meeting, which demonstrates the location and grades of the deformity and various methods of treatment. Any physician who visits this demonstration may in a few moments familiarize himself with the clinical and roentgenologic appearances and have at his command the means of relief of symptoms. There is but little justification for continued lack of recognition of this deforming and disabling lesion.

### CHIEF COMPLAINTS

Backache was the chief complaint in more than 80 per cent of 583 cases. Pain was projected to the sacroiliac area, hips and legs in 17 per cent of cases; an additional 7.7 per cent of patients had pain in the legs only, and less than 2 per cent complained of deformity, stiffness or paralysis. Although some of the patients may have had tingling and numbness, weakness or a feeling of stiffness in the legs, true paralysis was rarely found. The average duration of symptoms was 7.5

From the Section on Orthopedic Surgery, the Mayo Clinic.  
Read before the Section on Orthopedic Surgery at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

years; the shortest duration was one day, the longest fifty years. Although it is difficult to understand, 10 per cent of the patients had no complaint and the recognition of the lesion was incidental to examinations for other diseases or deformities. The typical complaint was of backache, with disability on hard labor or on

Fig. 1.—Typical deformity of spondylolisthesis, showing depression, and forward and downward displacement of lumbar spine.

stooping and lifting. Slight stiffness and weakness of the back or pain in the legs with relief of symptoms by rest, especially recumbency, was a marked feature (table 1).

#### DIAGNOSIS

In many cases it is possible to make the diagnosis following inspection and palpation. A prominent spinous process and sacrum with lordosis due to forward and downward displacement of the spine and slight muscle spasm are often sufficient evidence to make one suspicious of spondylolisthesis. With lesser degrees of deformity these signs may be unrecognized, but they are always present in grosser displacements, when the shortened torso, prominent erector spinae muscles, broad-appearing pelvis, and abdominal crease accentuate them. Patients with extreme types of spondylolisthesis may list to the side or may waddle when they walk, and the ribs may rest on or telescope into the pelvis; in such cases the diagnosis may be made from inspection alone. Proctoscopic examination may reveal a narrowed pelvis as a result of a hard, fixed mass projecting forward from the spine; in women this may cause difficult labor at childbirth. Pain on lifting and stooping, on being jarred and on carrying heavy objects, which pain is relieved by recumbency, is the common subjective symptom. A few patients have noticed a decrease in height.

Although I feel confident that the diagnosis can be made from these observations, as has been said one must rely on the roentgenologic examination for accurate grading of the degree of deformity and for deter-

mining the site affected and the type of anomalies present, which may be factors in its production. Roentgenologic examination will exclude tuberculosis, fractures, arthritis and tumors. Anteroposterior roentgenograms cannot be relied on to disclose forward displacement; lateral roentgenograms permit gaging of the exact degree of deformity.

Roentgenograms should include the lumbar spine and sacrum. Those familiar with the interpretation of anteroposterior roentgenograms may note the shortened lumbar spine, the superimposed fifth lumbar vertebra on the sacrum, the cocked-up spinous processes, separation of the neural arch, and spina bifida. In the lateral roentgenograms the degree of subluxation may be determined and graded 1, 2, 3 or 4, as in figure 2. To differentiate traumatic from congenital deformities may require roentgenograms taken at an angle of 45 degrees. Smooth, jointlike fissures are usually congenital, whereas irregular, sharp outlines are more suggestive of fracture. One also notes the angle and width of the lumbosacral joint, the condition of the promontory of the sacrum (whether rounded or elongated) and the presence of lipping along the margins of the vertebral bodies. Sclerosing of the articular facets, the length of the neural arch, evidence of fracture or of congenital deformity such as separation, are all observations which influence one's decision as to the etiologic and complicating factors present. A study of the roentgenograms can be carried out best in a moderate degree of light, and special attention should be paid to the contour of the spinal canal where the displacements are often more readily made out. The fifth lumbar vertebra is commonly found to be wedge shaped and the sacral portion elongated, concave and riding forward on the sacrum. The promontory of the latter may impinge

Fig. 2.—Four grades of spondylolisthesis.

between the body and the posteriorly displaced spinous process. The remarkable variation in the lumbosacral angle, which can vary fully 60 degrees, is shown in figure 3.

#### OCCUPATION

About 70 per cent of this series of patients with spondylolisthesis were farmers, laborers or housewives. To my mind this confirms the important effect strain and trauma have on many people, who, had their employment been less strenuous, might have gone through life without symptoms. With the more common use of the roentgenogram an increasing number of

congenital defects have been observed in the region of the fifth lumbar vertebra. When repeated strain or sudden trauma weakens the stability of these parts, symptoms arise and disability results. At the clinic we have observed that more than 10 per cent of patients have spondylolisthesis without being aware of it. The

inferior articular facets of the fifth lumbar vertebra resting on the superior articular facet of the sacrum, with intact lamina and ligamentous support, should prevent the body of the vertebra from slipping forward. Separation of the neural arch, however, is a very common observation and it is this loss of the support to the facets which seriously impairs the strength of the lumbosacral joint, resulting in subluxation, with strain on the ligaments, stretching or pressure on nerves, abnormal posture, muscle spasm and fatigue. It is interesting to note that not only 70 per cent of our patients who had spondylolisthesis were those that did hard work but almost 70 per cent of our patients were males. Thus the past teaching that the lesion is more frequently found in females is contradicted and the strain of the laborer has supplanted the labor of pregnancy as an etiologic factor (table 2).

AGE AND SEX INCIDENCE

Fifty per cent of our patients with spondylolisthesis were between the ages of 30 and 40 years and 70 per cent were males. The average age of the males was 40.3 and that of the females 43.5 years. The oldest patient was 80 years old, the youngest eleven years (table 3). No doubt the age and sex incidence will vary with the type of practice. I have had roentgenograms of this condition in younger patients sent to me, and Kleinberg has reported one case in a child only 18 months of age.

GRADE OF DEFORMITY AND TRAUMA

A history of trauma was obtained in about 48 per cent of the cases in this series (table 4). The fact that a patient may state that he has had an injury to his back is not sufficient evidence to conclude that subluxa-

tion is the result of the injury. On careful inquiry we have found that the patient sometimes has had chronic backache for months or years prior to the injury but that, following trauma, it had become more troublesome. The type of injury likewise was often of such a nature that it could not possibly have been a factor in the causation of the deformity. In cases in which compensation is of prime importance, the patient may attribute his symptoms to trauma and deny having had backache or disability previously in the hope of obtaining financial gain. In some cases the history furnishes irrefutable proof of the traumatic nature of the condition. When doubt exists as to the cause of pain in the extremities, neurologic examination, including studies with iodized oil and examination of the spinal fluid, may be indicated to rule out the possibility of a cord tumor, slipped intervertebral disk or thickened ligamentum flavum. I attempted to ascertain the effect of trauma on the grade of deformity but was unable to establish a definite relationship. Spondylolisthesis of grade 4 following trauma is no indication that the injury is responsible for the marked deformity, for an equal number of patients with spondylolisthesis of grade 4 had no previous history of trauma (table 4). I have attempted to group the various degrees of subluxation in this series of cases into four grades. The grade or degree of deformity in spondylolisthesis is determined by the examination of lateral roentgenograms; if the fifth lumbar vertebra has slipped forward

less than a fourth of the distance across the lumbosacral joint the spondylolisthesis is graded 1; if it has slipped less than half the distance it is graded 2, if it has slipped less than three fourths of the distance it is graded 3, and if it has slipped more than three fourths of the distance it is graded 4.

Of 442 patients whose degree of deformity was graded, 200, or 45.2 per cent, had spondylolisthesis of

grade 1, and it occurred at the lumbosacral articulation; in forty-seven cases, or 10.6 per cent, the degree of deformity was graded 3 and 4. In 93.4 per cent of the 583 cases in the series the deformity occurred at the level of the fourth and fifth lumbar vertebrae or at the level of the fifth lumbar vertebra and sacrum (table 5).

Fig. 3.—Variations in lumbosacral articulation (made from roentgenographic tracings): the lumbosacral angle can vary fully 60 degrees. The sacral angle may be rounded and the inferior aspect of the fifth lumbar vertebra may be concave. Congenital defects of the lumbar region, such as spina bifida and defects of the neural arch, are common.

#### LOCATION OF DEFORMITY

In 82 per cent of the cases in this series the deformity consisted of forward slipping of the fifth lumbar vertebra on the sacrum (table 6). Spondylolisthesis occurs at other levels and in this series it was found that sixty-six patients, or 11.3 per cent, had slipping forward of the fourth lumbar vertebra on the fifth. Less than 1 per cent had involvement of the third and fourth lumbar vertebrae or of the second and third lumbar vertebrae, or of the fifth and sixth lumbar vertebrae, or of the sixth lumbar vertebra and sacrum. One had double displacement, which consisted of two spondylolistheses occurring in the lumbar spine; that is, spondylolisthesis of the fourth lumbar vertebra on the fifth and of the fifth lumbar vertebra on the sacrum. A larger number of the group, twenty-six patients, or 4.4 per cent, had deformity consisting of reverse spondylolisthesis; in this group the vertebra involved is displaced backward instead of forward. This type of spondylo-

Fig. 4.—Rocking-chair type of back support made of steel and leather.

listhesis gave rise to the definition, which I have stated previously, "spondylolisthesis is a subluxation, usually forward, and most commonly in the lumbosacral region, where it may produce narrowing of the pelvis."

#### TREATMENT

In those cases in which spondylolisthesis occurs as a result of trauma and this is recognized immediately, an attempt should be made to reduce the deformity

by traction and prevent its recurrence by casts. In cases in which the patient is placed in a recumbent position and traction, by means of Buck's extension, is applied, some improvement in the position of the vertebral bodies and relief of symptoms may be expected. With the legs elevated and at right angles to the thighs, and with the thighs at right angles to the recumbent spine, the weight of the torso may be utilized in pulling the vertebral bodies into better position. The insertion of a Kirschner wire through the lower end of the femur maintains this position easily and the danger of irritation of skin is obviated. This position is maintained for six weeks, and following this a plaster cast may be applied, with the legs in extension, in the form of a double spica cast extending up to the axilla. This permits the patient to be moved about or turned over on his abdomen or side; by so doing the occurrence of pressure sores is avoided. The patient is kept in this cast for a further period of six weeks. At the end of this time a lumbosacral support is applied and the patient is allowed up and permitted to walk with crutches. Should

Fig. 5.—Operative procedure to produce strong fusion of the lumbar spine (including third, fourth and fifth lumbar vertebrae and sacrum) by means of double massive bone grafts, multiple bone chips and cancellous bone.

there be recurrence of the subluxation, the spine is better fused by bone grafting, as will be described in a subsequent paragraph.

As some patients do not have symptoms or have only mild symptoms that do not cause disability, a corset reinforced by stays to support the lumbosacral spine is all that is required. In the treatment of women, we employ a strong reinforced corset and, for men, a rocking-chair or canvas belt reinforced with steel type of support (fig. 4). Many patients obtain marked relief from such apparatus and continue to carry on their work; in some cases, however, symptoms continue and fusion of the lower lumbar spine and sacrum is then indicated. Most patients who follow a laborious occupation are subject to such repeated strains and injuries that a change of occupation or an operation is necessary. But I wish again to state that there are some patients who in spite of marked deformity, of grade 3 or 4, go on working at hard labor without symptoms. In some of these cases roentgenographic studies may show that the sacrum has built up a shelf to aid in the support of the fifth lumbar vertebra; in

others, arthritic changes have apparently produced fusion in the affected region. It is apparently true that many patients have never known what a normal back feels like and have continued to work in spite of discomfort and pain.

In order to support adequately the lumbosacral subluxation and prevent further displacement, the fusion resulting from operation must be strong enough to stand the stress and strain of hard labor. As the fifth lumbar spinous process is loose and its fusion alone to the sacrum is of no value, one must go above and fuse the third, fourth and fifth lumbar vertebrae and the sacrum securely (fig. 5). To accomplish this an incision is made from the third lumbar spinous process to the second sacral segment and, with a sharp chisel, fragments of bone are turned from the sides of the processes and the laminae. With retractors in place, the chips of bone and muscles are pulled to one side and the laminae scraped so as to carry some of the bone fragments laterally. Packs of gauze soaked in hot saline solution are then placed in the cavities on either side of the spinous processes and attention is given to further roughening of the laminae and exposing the articular facets; the last named, whenever possible, are curetted to remove cartilage from their articular surfaces. As each facet is destroyed, a pack is firmly pressed into

Fig. 6.—Sagittal sections through the lumbosacral area with shading of the dural sac to show pressure on the cauda equina by the displaced vertebra: a, normal spinal canal; b, grade 2 spondylolisthesis of fifth lumbar vertebra on sacrum; c, grade 3 spondylolisthesis of fifth lumbar vertebra on sacrum; d, grade 1 spondylolisthesis of fourth lumbar vertebra on the fifth.

position and the next one is exposed. The object of this roughening is to produce extensive raw surfaces of bone to which the grafts will readily adhere. Care must be taken not to perforate the spinal canal, as spina bifida of the sacrum is often present (fig. 6).

The sacrum is then roughened and a sharp chisel is used to lift thin fragments of bone. When the bed has been thus prepared, it extends from, and includes, the third lumbar vertebra to the third sacral segment. All the soft tissues between the exposed bones are removed. A long incision is made mesial to the tibial crest and a bone graft is removed; this graft, when divided, is of sufficient length to pass from the third lumbar vertebra to the third sacral segment. At times it is necessary to cut grafts with a slight curve so as better to fit them into position; the curved rim of the ilium may be used instead of tibia.

A large curet is employed to remove cancellous bone from the upper end of the tibia; from six to eight masses of cancellous bone are removed and packed in to fill the spaces between the vertebrae. The two grafts are then inserted, one on either side of the spinous processes and over the exposed sacrum, and held by interrupted sutures of number 2 chromic catgut. These sutures approximate the soft tissues, to which numerous small fragments of bone have been left attached, thus

forming a bony bridge over the grafts, denuded spinous processes and laminae. The subcutaneous tissue is sutured with number 1 plain catgut, the needle picking up just enough of the deep fascia to obliterate dead space under the skin. The skin is closed with a continuous dermal suture, and a moist alcohol (70 per cent) gauze dressing of ten or twelve thicknesses is applied.

A layer of absorbent sterile cotton of sufficient size to extend 4 inches (10 cm.) beyond the gauze is fastened by strips of adhesive tape so as to prevent contamination along the edges.

The patient is then placed on a canvas frame, face downward, and taken to bed; by means of overhead apparatus consisting of ropes and pulleys one nurse is able to raise and lower the patient for various nursing purposes. The patient is kept in the first position, that is on his abdomen, for a period of twenty-four hours and is then turned over several times a day thereafter. Stitches are removed at the end of two weeks. We prefer to keep our patients in bed and on the frame for a period of six weeks, when they are given a lumbosacral support and allowed to walk. When this technic is meticulously carried out, the resulting fusion is excellent, as may be seen from the antero-posterior and lateral roentgenograms, and it extends from the third lumbar vertebra to the third sacral segment. This operation has been performed on ninety-nine patients with gratifying results and we believe that it is the method of choice for all painful and disabling

subluxations of the lumbosacral articulation or other affected spinal levels. There was no operative mortality in this series (table 7).

SUMMARY

In a series of 583 cases of spondylolisthesis involving the lumbar spine the principal complaint was backache or backache and aching in the legs. The average age of the patients was about 40 years and the average duration of symptoms seven and a half years.

About 70 per cent of the patients in this series were males, which contradicts the older teaching that spondylolisthesis occurs most often in females. The condition most frequently affects those who perform hard labor. It may be of traumatic origin or result from congenital abnormalities which have weakened the supporting structure in the lower part of the back.

Although the condition often escapes detection, the deformity can be readily recognized, at times from mere inspection and palpation. It may be proved and graded as to degree of subluxation on examination of lateral roentgenograms. A method of grading spondylolisthesis has been adopted that will permit physicians to transmit the location and extent of subluxation in an easily understood manner.

Congenital and traumatic types of spondylolisthesis must be differentiated, as this is of prime medicolegal significance in dealing with insurance companies and workmen's compensation commissions.

Not all patients who have this deformity complain of symptoms. More than 10 per cent of those included

in this series had no symptoms referable to the back. As the degree of subluxation increases to complete dislocation, the shape and angle of the lumbosacral articulation is altered. Paralysis is not commonly found, although paresthesias and referred pain to the saddle area and legs are frequent complaints.

An operation has been devised which prevents further displacement and relieves symptoms, permitting the patient to return to gainful labor.

### ABSTRACT OF DISCUSSION

DR. S. L. HAAS, San Francisco: Dr. Meyerding's paper has so well supplemented his scientific exhibit that there remains little to be discussed. Operations on children may demand special consideration, because a graft over the posterior surface would hinder growth while the bodies would continue to increase in size. There may be an increased force forward, and the displacement may become greater. The anterior bone block across the bodies of the vertebrae would be more satisfactory, as it not only would give the support where it was needed most but would tend to stop the growth of the bodies. I hope that Dr. Meyerding will add something further with regard to the treatment of spondylolisthesis in children.

DR. CHARLES LEROY LOWMAN, Los Angeles: For diagnosis roentgenograms are essential in confirming certain clinical appearances which should tentatively make one suspect the

existence of the condition: (1) the absence of a posterior rounding of the lumbosacral curve on bending forward, (2) an exaggerated lumbar curve on standing, (3) the feeling to the palpating hand when the patient lies prone of a sharp dip forward from the posterior prominence of the first sacral vertebra into a hollow over the lumbosacral junction or (4) inability of the patient when lying supine to hold the extended legs in semiflexion without pain at the region of the lumbosacral junction or a feeling that he is "giving away" at that point. I should like to call attention again to the importance of roentgenograms taken laterally with the patient in the standing position to bring out the slippage in mild grades of this deviation. In severer grades the position of displacement will be fixed by muscle spasm or ligamentous shortening and can be detected readily in the lateral view taken with the patient lying down. However, it should be appreciated that, as the pelvis changes its degree of obliquity from the standing to the lying position and loses usually any lateral tilt which may exist because of short legs or structural discrepancies in the sacrum or ilium, a view showing the actual influence of the gravity load will give valuable information. Dr. Meyerding has called attention to the high incidence of congenital faults in this region; the addition of any unusual stress added to the existing weakness, which may previously have been tolerated, can easily be the factor which produces the further displacement or provokes the pain or disability which brings the patient to the physician. The common existence of flattened interarticular processes on the first sacral vertebra is, I think, an important element, because as increased obliquity occurs in the anteroposterior plane, mechanical locking is decreased and the load on the ilio-lumbar and anterior vertebral ligaments is increased, raising the possibility of displacement under stress. With regard to the operative phase, orthopedic surgeons have all experienced difficulty in obtaining true arthrodesis at this point, and I have been greatly impressed by the value of Dr. Meyerding's procedure in putting in so much bone over a large enough area to obtain this massive repair.

DR. J. ALBERT KEY, St. Louis: I should like to ask Dr. Meyerding to state what patients he operates on and what ones he recommends for conservative treatment.

DR. JOHN DUNLOP, Pasadena, Calif.: I should like to ask what influence the diagnosis has in compensation cases as to the cause.

DR. HENRY W. MEYERDING, Rochester, Minn.: It is interesting to note that backache was the principal symptom in more than 80 per cent of these cases of spondylolisthesis and that in almost an equal percentage of cases the occupation of the patient required heavy labor. The average age of the patients was more than 40 years, and the average duration of symptoms was about seven and one-half years. These studies have proved that the strain of pregnancy is no longer a principal etiologic factor. I believe that congenital anomalies are the principal factors in the production of spondylolisthesis and that the stress and strain sustained by patients whose occupation is concerned with manual labor are exciting factors. The condition occurred in the lumbosacral region in more than 80 per cent of the cases in this series. More than two thirds of the patients were males; this contradicts the previous teaching that the condition occurs more frequently in females. My associates and I have operated in less than a fifth of this series of 583 cases. Ten per cent of the patients had no symptoms referable to the back, and the diagnosis of spondylolisthesis was incidental to examinations carried out for other symptoms. Many of the patients who had not been disabled were relieved of their backache by the use of lumbosacral supports; this type of support is reinforced by steel stays and fits well down onto the sacrum and upward onto the lumbar vertebrae. When the occupation required activity and the patient was likely to have increasing symptoms and deformity with disability, we advised surgical fusion. The operation produces a huge mass of bone, which results in firm, bony fusion of the sacrum and the third, fourth and fifth lumbar vertebrae. Acute traumatic spondylolisthesis is treated by overhead traction by means of a Balkan frame. We have not observed any untoward results in patients who have been treated by the surgical method described. The patients were all adults who had had backache for a number of years.

THE ONE STAGE COMBINED ABDOMINO-  
PERINEAL RESECTION OF THE  
RECTUM

FRED W. RANKIN, M.D.

LEXINGTON, KY.

The choice of offensive against cancer of the rectum and rectosigmoid at the present time indubitably is surgical intervention. That the extirpation of cancer in this location can be done in conformity with the fundamental principles of radical operations for cancer elsewhere is equally true. It is axiomatic, however, that cancers low in the gastrointestinal tract demand an unusually high individualization so far as operative maneuvers are concerned. No one technical procedure is applicable to all malignant growths in this location, and many factors, including coexisting debilitating diseases, the ability of the patient to withstand formidable surgical intervention and the undermining influences of malignant processes in general must influence the choice of operation.

The well known tendency of cancers of the rectum to develop on adenomas and areas of local hyperplasia, the slow evolution of the concurring malignant process, its tendency to be of a relatively low order of cellular activity and consequently to invade lymphatics late, all allow the surgeon a remarkable latitude in the selection of operative plans.

Individualization of treatment is a paramount necessity in dealing with cancer of the rectum, and for this reason no one type of operation is applicable as a matter of routine without an excessive reduction in the operability figures and a probable increase in the mortality rate. To insure that as many as two out of three or even three out of four patients as they present themselves for examination will be subjected to operative removal, one may employ, first, the radical combined abdominoperineal resection or the perineo-abdominal operation in one or two stages; second, colostomy and posterior resection as advocated by Mummery, and, third, local excision with or without segmental resection and with or without preservation of the sphincter.

For the last-named type of operation I have small enthusiasm, believing that a colostomy is a necessary part of any operation which will give a high percentage of satisfactory end results. Colostomy does not entail social ostracism or professional incapacity, but there is a certain stigma attached to it and the preservation of the rectal sphincter in a small group of properly selected cases, namely those in which the cancer is of low pathologic grade and without metastases, is the desire of both surgeon and patient. The great difficulty in making this selection is to tell without resection which growth has remained local and which has metastasized, but the high percentage of glands now found involved in the resected specimens indicates that the crux of the situation from the standpoint of prognosis still remains a question of glandular involvement at the time of operation.

The work of Miles<sup>1</sup> on the lymphatics of the rectum still stands, I think, as a classic on which is predi-

cated the logic for removal of gland-bearing tissues even to the height of the mesentery of the sigmoid flexure. Westheus<sup>2</sup> recently published the report of an exhaustive investigation of the lymphatics of the rectum in relation to the spread of cancer, in which he disagrees with Miles that the downward spread is of frequent occurrence. While this type of spread may permit the utilization of an operation to save the sphincter mechanism in certain closely selected cases, actually the vast majority of invaded lymphatics are in the upward zone of spread, and the most recent investigations by Gabriel, Dukes and Bussey,<sup>3</sup> David and Gilchrist,<sup>4</sup> and others prove conclusively that a higher percentage of invaded lymphatic glands are now being found by more extensive and exhaustive methods of search. In my own series of 139 cases in this study, the glands were involved in 55 per cent of the specimens.

At the St. Mark's Hospital, Gabriel, Dukes and Bussey,<sup>3</sup> making an extensive examination of 100 excised rectums and investigating an average of twenty-eight glands in each case and in some instances as

Fig. 1.—Beginning of mobilization and dissection of the pelvis. An incision in the peritoneal covering of the mesentery on its right side has been made from the inferior mesenteric vessels down to the bladder. The right peritoneal leaf is to be dissected further to form one half of the pelvic floor. Ligation of the inferior mesenteric vessel above the superior hemorrhoidal artery is shown. Both ureters are exposed.

many as sixty glands, found that 62 per cent of the resected specimens showed involved glands. David and Gilchrist<sup>4</sup> reported before the American Surgical Association in May 1938 isolation of between fifty and eighty glands to a resected specimen in their series of cases, with evidence of glandular involvement in 70 per cent. These studies seem to indicate accurately that extensive and thorough investigation proves the incidence of glandular involvement to be much higher than was formerly believed, and they emphasize the necessity of extensive removal of gland-bearing tissues.

The principles laid down by Miles<sup>1</sup> for his radical combined abdominoperineal resection, and consummated as radically by Grey-Turner, Gabriel and their British colleagues in their perineo-abdominal resection, more nearly, I think, answer the full requirements of radical surgical intervention than other types of operation.

Read before the Section on Surgery, General and Abdominal, at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

1. Miles, W. Ernest: *Cancer of the Rectum*. London, Harrison & Sons, Ltd., 1926.

2. Westheus, quoted by Bastianelli, R.: *Deutsche med. Wchnschr.* 63: 1254-1259 (Aug. 13) 1937.

3. Gabriel, W. B.; Dukes, Cuthbert, and Bussey, H. J. R.: *Brit. J. Surg.* 23: 90 (Oct.) 1935.

4. David, V. C., and Gilchrist, R. K.: Personal communication to the author.

The advantages of the combined operation may be summarized as follows:

1. It conforms to the principles of radical extirpation of cancer elsewhere, removing the local growth and tissues in the zones of spread.
2. It permits of variations and modifications to be done in either one or two stages.
3. It may be accomplished either as an abdominoperineal or as a perineo-abdominal operation.

Fig. 2.—The pelvic dissection further advanced. Both the right and the left peritoneal flaps are demonstrated, the tumor is shown at the recto-sigmoid junction, where two thirds of all rectal cancers occur, and the beginning application of the Zachary-Cope de Martel clamp is illustrated. This clamp consists of three independent, biting blades with end catches to hold them in place and is applied in a removable crushing instrument.

4. With increasing experience on the part of the surgeon, the operability curve may be broadened and at the same time the hospital mortality remain below 10 per cent.

5. Five year end results from the clinics of the most experienced advocates of the radical combined procedures indicate a higher percentage of five year cures than for the other types of operation.

6. Only one laparotomy is required, so that time and expense are saved for the patient.

7. The blood supply to the growth may be ligated before the pelvic dissection is undertaken.

8. The procedure is applicable to all ampullary and recto-sigmoidal cancers.

The disadvantages may be summarized as follows:

1. It has been argued that the operation involves a higher mortality than the less radical procedures.
2. The operation bears the stigma of a colostomy.

#### PREOPERATIVE TREATMENT

Meticulous and carefully planned routine pre-operative measures unquestionably greatly facilitate the operative act. The patient should in every instance (except when acute intestinal obstruction is present) be hospitalized from five to seven days. It is my plan not to have the patient in bed but to allow him to be ambulatory and to direct all efforts toward decompression of the bowel by means of purgation and enemas. These measures are continued until twenty-four hours before operation, when the patient is given camphorated tincture of opium or lead and opium pills to allay peristalsis. I do not use continued

purgation but prefer to give one large dose of castor oil at the beginning of the preparatory period and follow this by multiple daily washings with physiologic solution of sodium chloride. The usual tests are repeated as often as necessary to insure proper balance of the blood chemistry. Transfusions are resorted to when they seem necessary but are not used as a matter of routine before operation. A large amount of dextrose in the diet is insisted on. The routine cardiac and renal function observations are made, and rehabilitation during this period of decompression is forwarded by whatever means are possible.

#### TECHNIC

The abdomen is opened through a long low median incision which passes from the symphysis to a point about 2 inches above and to the left of the umbilicus. In all, the incision is about 10 to 12 inches in length. As soon as the peritoneal cavity is open the left hand is thrust upward to the liver to begin exploration of the abdomen from above downward. The surfaces of the liver are felt, the gallbladder is examined and the glands along the aorta, the common iliac vessels and, lastly, the growth itself are explored. The growth is tested for mobility, its operability determined and the procedure of resection begun.

The importance of the deep Trendelenburg position cannot be overemphasized, since it facilitates the packing off of the pelvis, which is exposed by a spreading, self-retaining retractor. In a woman the uterus is held up out of the top of the wound with a blunt hook, so that the bottom of the pelvis is easily exposed.

Fig. 3.—The dissection completed, the clamp in place and the end catches closed. The inset shows the middle blade removed and the division of the bowel by the cautery. Adequate blood supply to the proximal end, which forms the colostomy, is demonstrated under visual inspection.

The loop of the sigmoid flexure is drawn to the right to expose the natural adhesions between the peritoneum and the mesentery of the sigmoid flexure. These are divided by sharp dissection. It will be remembered that the colon ascends in fetal life from the pelvis and usually lies in the left side of the pelvis; as it emerges

the lateral part of the parietal peritoneum and the mesenteric covering are fused at the level of the pelvic brim.

After mobilization of the sigmoid flexure, the peritoneal covering of the left side of the mesocolon is divided about  $1\frac{1}{2}$  inches from its peritoneal reflection from a point opposite the main trunk of the inferior mesenteric vessels downward into the pelvis. This

Fig. 4.—The colostomy established through a stab wound in the left groin. The tumor and the distal segment of bowel are dropped down into the pelvis, and a new pelvic floor is made by closing the peritoneal flaps. In the woman the tubes and ovaries give additional support to the pelvic floor. It is essential that all raw surfaces be covered.

incision is then extended laterally below the brim of the true pelvis and well into the parietal peritoneal covering and from there anteriorly to encircle the pouch of Douglas in the female or the rectovesical space in the male. The anterolateral portion of the peritoneum is then dissected free by blunt dissection to form the left half of the new pelvic floor. At this point the left ureter is identified, having been clearly exposed by the removal of the lateral reflection of the parietal peritoneum. It will be noted that a great deal of the mesentery has been denuded of peritoneum by this procedure. All of the mesentery of the lower two thirds of the sigmoid flexure is sacrificed.

The right side of the pelvis is then exposed, and in a similar manner sufficient peritoneum is dissected free to form the right half of the new pelvic floor. The right ureter is then isolated, although there is much less danger of ligation on this side because it normally courses farther outward over the large vessels. The gland-bearing tissues and retroperitoneal fat from the bifurcation of the aorta outward and down over the hollow of the sacrum are swept mesially to insure a clean dissection of the entire pelvic lymphatic supply of the rectosigmoid.

Dissection is then carried forward into the tissue plane which separates the seminal vesicles and prostate or the posterior vaginal wall, as the case may be, from the anterior surface of the rectum. With this mobilization carried well down into the pelvis, an anterior peritoneal flap is then created to complete the new pelvic floor.

With the hand placed in the hollow of the sacrum, finger dissection is carried still farther downward, with

a division of the posterior ligamentous attachments to the point where the fascia propria of the rectum fuses with the periosteum of the sacrum at the sacrococcygeal articulation. Lateral dissection is carried out with the scissors, visualization being aided by the Kameron light. In severing the lateral ligaments one must remember that the middle hemorrhoidal arteries are concealed in them. Usually they are so small that hemorrhage does not occur, but in about 10 per cent of the cases they are found to be medium-sized vessels which require ligation.

The blood supply of the entire segment of the bowel is then identified, caught in clamps, divided and doubly ligated, the inferior mesenteric vessels being tied below the superior hemorrhoidal branch. The field is carefully inspected to avoid inclusion of the left ureter in this clamp. The left colic artery is protected to insure adequate blood supply to the proximal end of the bowel, and under direct vision the point of division of the bowel is located with relation to the pulsation of the small vessels. The vascular arcades are ligated individually, as the mesentery is then divided up to the intestine. The de Martel-Cope clamp is applied to the bowel after demonstration of an adequate blood supply to the proximal end. After the bowel is crushed the two end blades of the clamp are left on, the middle blade removed and the bowel divided with the cautery. The pelvis is cleanly dissected, and the entire loop of bowel to be removed is thrust down into it and covered over by the newly formed pelvic floor. The peritoneal flaps are approximated with a running suture of chromic catgut, and this is reinforced with a second line of sutures. When the patient is a woman the

Fig. 5.—The beginning of the posterior removal of the entire bowel segment. The rectum is closed with a purse string suture, and two curved incisions extending from the coccyx to the center of the perineum encircle it. The coccyx is removed, the perirectal fat is included in the dissection and the levator ani muscle is sacrificed.

uterus, tubes and ovaries are dropped over the line of sutures, further strengthening it.

The next step is the colostomy. I prefer to follow Miles's original procedure and make the opening in the left groin through a separate incision, closing the midline incision. A circular piece of skin about  $1\frac{1}{2}$  inches in diameter is excised from the anterior superior

spine of the ilium on a line with the umbilicus. After removal of the skin the incision is carried directly downward through the musculature of the abdominal wall, and just enough opening is made to allow the proximal end of the bowel to be drawn out easily and yet to be held snugly by the peritoneum. Two or three interrupted sutures between the peritoneum and the

Fig. 6.—The pelvis has been opened by division of the fascia propria, and the bowel segment containing the tumor is being delivered.

epiploic appendages and mesenteric fat of the bowel are all that hold it in the wound. Care is taken not to penetrate the coats of the bowel itself with sutures. The de Martel-Cope clamp blade is left on, obstructing the bowel for thirty-six hours, until adhesions have formed between its peritoneal surface and danger of leakage is past. The wound is closed in layers and the colostomy opening is surrounded by petrolatum gauze packing and incorporated in a separate set of dressings.

The second stage is done with the patient in the posterior resection position with the hips well elevated. The anus is closed with a running suture of strong silk. Two semilunar incisions extending from just above the sacrococcygeal joint to midway of the perineum are made encircling the anus. The dissection on each side includes the fat in the ischioanal fossa. Dissection is carried down laterally on both sides to and through the levator ani muscle before the anal canal is separated from the vagina in the woman or the prostate in man.

The lowermost part of the dissection is done by cutting through the perineal body separating the rectum from the vagina or prostate. Practically all the second stage is finished before the pelvic cavity is again opened. The sacrococcygeal articulation is divided, the coccyx being removed in all cases. The branches of the middle sacral artery frequently bleed at this point and should always be ligated. The fascia propria is then divided to open the cavity of the pelvis. The whole segment of bowel is delivered, the pelvic cavity filled with a sponge saturated with mercury bichloride solution and the bleeding points all carefully and accurately ligated.

The cavity left by the resection is filled with a gauze pack encased in a sheet of oiled silk. This pack serves two purposes, first to support the pelvic floor and, second, to prevent oozing. One half is removed at the end of thirty-six hours and the remainder at the end of seventy-two hours. The silk shield prevents any adhesions to the tissues and makes the removal of the pack painless. The wound is closed very loosely with silkworm sutures. An attempt is made only to cover the open end of the sacrum where the coccyx was disarticulated. The entire wound is expected to heal by granulation.

#### POSTOPERATIVE CARE

All patients are given a transfusion of 500 cc. of citrated blood immediately after operation. Forty-eight hours after the removal of the pack from the posterior part of the wound, irrigations of the cavity with warm saline solution or potassium permanganate solution are started, to be given daily. The colostomy opening is treated in the ordinary way without irrigation, and the bowels usually move spontaneously after the fourth day. Hydration and feeding are usually by venoclysis until seventy-two hours has elapsed. Once gas is passed from the colostomy, food is given by mouth. Healing by granulation is slow but is usually complete in from six to eight weeks except for a small, superficial area.

#### OPERABILITY AND MORTALITY

Since June 1934, when I did the first Miles operation in this series, I have operated on 139 private patients for cancer of the rectum and rectosigmoid. Of the resections, seventy-five were done by Miles's technic

Fig. 7.—The inset shows the wound closed loosely with interrupted sutures, while the main figure shows the drainage in place. A huge dam of oiled silk is pushed into the pelvic cavity and filled with gauze packing, the one half of which is removed at the end of forty-eight hours and the remainder in seventy-two hours. The pack not only prevents oozing but supports the pelvic floor until exudate makes it firm. Its removal is painless.

in one stage, six by my own type of two stage combined perineo-abdominal resection and twenty-five by Mummary's operation of colostomy and posterior resection. The Miles operations were done with five deaths, a mortality of 6.6 per cent. The causes of death were pulmonary embolism (confirmed post mortem) in two cases, peritonitis (confirmed post mortem) in two cases and cerebral thrombosis (hemiplegia twelve hours postoperatively) in one case.

Resection was done in 106 of the 139 cases, a resectability figure of 76.2 per cent. Thus it will be seen that approximately three fourths of the resections in this series were done by the one stage combined abdominoperineal method, indicating its applicability in a high percentage of cases in which meticulous preoperative care, careful operative technic and personal postoperative supervision are combined. It is an operation which calls for team work not only in the operating room but in the wards and because of the necessary cooperative management probably will not become a routine operation except in the hands of surgeons in whose practice a large group of rectal cancers are encountered.

#### PROGNOSIS

The prognosis depends largely on extension of the growth, and whether one estimates this by Broders' type of grading or by Dukes' method, the end results are much the same. Fortunately, the largest percentage of cancers of the rectum are of grades 1 or 2 and remain local a considerable length of time. Statistical data furnish ample evidence that radical extirpation of the rectum by the combined abdominoperineal resection or the combined perineo-abdominal operation gives a higher percentage of five year cures than the less radical procedures. However, one should consider operability percentages along with mortality curves when evaluating postoperative results, for a cautious and not widely experienced surgeon may consider a growth inoperable because of fixation, which a more experienced and daring surgeon would readily attack. It follows that definite attempts should be made to elevate the operability figure by including questionable and borderline cases so long as they do not raise the hospital death rate beyond 10 or 12 per cent.

In October 1935, before the American College of Surgeons, Abel<sup>5</sup> reported on a series of 164 radical operations; 104 of the patients, or 63.4 per cent, were alive and well five years later. Thomas E. Jones<sup>6</sup> of Cleveland presented before the same assembly a series of 151 cases, in 52 per cent of which the patient was living and well five years postoperatively.

The colostomy and posterior resection, a valuable operation applicable in a wide range of cases, has in my hands given a smaller percentage of five year cures. In June 1933, before the Section on Surgery, General and Abdominal, of the American Medical Association, I reported from the Mayo Clinic 300 cases of posterior resection, in 36 per cent of which the patient was well after five years. Mummery reported a higher percentage of satisfactory results from his operation and, using Dukes' grading, found that survivals for all grades numbered 52.5 per cent of the five year cures.

From these figures, if one considers the stage of the tumor at which operation is undertaken, it seems that the curability curve is raised by the radicalness of the operation, and, by the same token, that multiple operations are necessary to insure a high percentage of resections.

Radical surgical intervention may be accomplished more satisfactorily by the combined method of resection, but the utility of other types of operation is undeniable. To both Miles and Mummery the surgi-

cal profession owes a debt of gratitude for their pioneering, fundamental work, and the operations of both men must certainly be included in any surgeon's armamentarium.

#### ABSTRACT OF DISCUSSION

DR. THOMAS M. JOYCE, Portland, Ore.: There is the liability to obstruction when the colostomy is made on the left side, unless the opening between the mesentery of the sigmoid and the parietal peritoneum is closed. I have been unfortunate in having this happen to me twice. Again, in making the opening through the abdominal wall for the colostomy it is very important that the slit through the fascia be adequate, for if this is tight it is likely to cut through into the bowel and there will be an abscess below the skin and in the abdominal wall. I have been unfortunate to have had this experience. I do not use sutures in the bowel. I have seen reports of these abdominal wall abscesses which were thought to be due to diverticula, but I believe they are due to an inadequate opening through the abdominal fascia. I have one more little procedure in the technic of removing the mesentery of the sigmoid which I remove high, in an effort to get all the gland-bearing area, just as thoroughly as I would in removing the axillary glands with a carcinoma of the breast: instead of attempting to put the whole sigmoid retroperitoneally, I remove this segment with the glands, and it usually amounts to about 8 or 10 inches. It is then very easy to put the distal segment retroperitoneally and close the floor of the pelvis without the least difficulty. Next I would mention the care of the colostomy. I do not believe in using any sort of container or rubber bag, such as one so often sees exhibited and advocated. With the usual cleaning out each morning, flushing of the sigmoid, using a pad of cotton over the colostomy opening and a thick canvas square which goes over the colostomy, with elastic bands around the abdomen to hold it in place, one will have no trouble whatever with discharge from the colostomy. Dr. Rankin mentioned that his operability was practically 76 per cent of the patients that come to him. I have a connection with a large municipal hospital at the University of Oregon where we have found the operability to be 23 per cent. At St. Vincent's Hospital, where the private patients come, our operability is 61 per cent. The longest span of life of those who were considered inoperable at the County Hospital was six months. It has been our practice to have adequate preparation of from four to six days, especially in decompressing the bowel, with preoperative blood transfusions, and in the majority of cases in which we are able to have adequate preoperative decompression we are able to do a one stage abdominoperineal resection. However, there are some cases among the elderly in which, even with adequate preparation, we have thought it advisable to do the two stage operation or the Mummery operation in two stages.

DR. HARVEY B. STONE, Baltimore: As Dr. Rankin stated, the Miles type of operation has definite advantages. It is true that it is a formidable procedure but experienced surgeons are performing it with a mortality of 10 per cent. This is not prohibitive considering the grave nature of the disease and the increased prospect of five year cures offered by this operation. One is somewhat surprised to read of the much higher mortality figures reported from some of the German clinics. In no sense of criticism, one may hazard the guess that this difference may be due to another point emphasized by Dr. Rankin, the essential importance of adequate preoperative preparation. Thorough clearing of the bowel beforehand, rest and building up of glycogen reserve, and the free use of transfusion of blood before and at the end of operation are probably more responsible for better immediate results than improved technical maneuvers in the operation itself. Nevertheless, in such a major surgical attack, skill, experience and well organized team work are of the greatest importance, and, as Dr. Rankin has hinted, men whose work does not provide fairly frequent opportunity to acquire these facilities may be reluctant to adopt the Miles operation. The fact that this is a single stage procedure and that it permits early control of the major blood supply of the whole field are other advantages Dr. Rankin has pointed out. But to my mind the greatest argument for the Miles type of

5. Abel, A. Lawrence: Five Year Cures of Cancer of the Rectum by the Radical Abdominoperineal Excision, Surg., Gynec. & Obst. 60: 481-482 (Feb. 15) 1935.

6. Jones, Thomas E.: The One Stage Abdominoperineal Operation for Carcinoma of the Rectum, Ann. Surg. 102: 64 (July) 1935.

attack is that this principle of approach alone allows adequate removal of the zone of lymphatic spread of the disease. Only by this method can one deal with cancer of the rectum in accord with those principles of surgical treatment of malignancy first established for the breast and now regarded as the best that surgery has to offer in the cure of cancer. It is true, as Dr. Rankin and other authorities always point out, that in the field of rectal cancer one cannot restrict oneself to a single method of operating. Variations in anatomic location, size of the lesion and condition of the patient all enter into the decision of the best way to handle each individual case, and certainly the one stage abdominoperineal resection cannot be universally employed. Nevertheless, where it is suitable it remains the best chance of permanent cure, when performed by experienced and competent surgeons. It is not appropriate to talk about details of technic at such a meeting as this, except to compliment Dr. Rankin on his clear and concise description. In only one point do I differ from him, preferring to do the second step of removal of the rectum from below in the exaggerated lithotomy position.

DR. THOMAS E. JONES, Cleveland: At the Detroit meeting eight or ten years ago I read a paper on this subject for this section. It was not very graciously received for the simple reason that it was thought that the procedure was too formidable and the mortality too high. However, it had seemed to me that the fault was not with the operation itself but with the fact that the preoperative treatment in this type of case had been inadequate. Following Miles, I kept these patients in bed eight or ten days and it was apparent that the chronically obstructed bowel could be decompressed with this method just as easily as by colostomy, and I started to do the combined abdominoperineal operation in one stage. It has been very satisfactory in my hands. With regard to the two stage operation, it has been my experience many times that when an exploratory operation was done and the condition seemed inoperable at that time, on reoperation in two or three weeks the condition found would be the same—inoperable. In the last 200 cases I have brought the colostomy out at the midline. The patients seem to like it better. I advise against the use of the colostomy bag but if patients insist on wearing a bag at least they look symmetrical and that is very important for the woman patient. In a series of 300 cases done in one stage, with an operability of 64 per cent, my mortality was 9.2 per cent. I am sure it is not only the technical maneuver, which is after all a small part of this, but also the preoperative care and care of the patient after the operation that contributes greatly to its success.

DR. FRED W. RANKIN, Lexington, Ky.: I am happy to have the gentlemen who discussed this paper agree that colostomy is not such an undesirable companion and is entirely compatible with a useful professional and social life. There are just two or three things to remember about a colostomy. One is that it has to be made properly, and in making it properly one has to take the slack out of the bowel and bring the loop out through as small an opening as is adequate. Secondly, care must be taken to obviate the possibility of herniation either of the mucosa or of the whole bowel. A hernia around a colostomy is very unpleasant. If these two technical steps are taken care of and the patient is put on a proper regimen and has the proper mental attitude toward the colostomy, I can imagine many things that are much more uncomfortable and disagreeable to possess. Dr. Joyce's point about obstruction following the making of a colostomy in the groin is well taken. I have seen this happen occasionally, but I believe the two factors most important in obviating it are, first, to have no raw surfaces in the neighborhood of the dissection which a loop of bowel can slip around and become adherent to; secondly, have a sufficiently large opening for the loop which is being utilized for the colostomy, or to close that lateral gutter with a single, continuous suture during the course of the operation. Also, these cups and general devices which are widely advertised are not only entirely unnecessary but largely undesirable. The colostomy should be adequately attended to and emptied, and the patient is kept on a diet which keeps away from loose stools. I think that proper attention to the colostomy in the morning, or occasionally in the evening, depending on the

patient's own choice, and an ordinary elastic supporter with a pad of cotton or gauze over the protruding mucous membrane are better. I agree with Dr. Stone as to bladder involvement being an indication of inoperability. I have four times removed a large portion of the bladder with a carcinoma of the low sigmoid successfully so far as the operative mortality is concerned, but the longest existence after any of these procedures was two years, and it is hardly worth while, to do a large, difficult job, when a palliative operation to relieve the patient would probably have done just as well. I question whether it is worth while attacking a carcinoma of the recto-sigmoid or the lower sigmoid which has already become adhered to and invaded the bladder. I wish to emphasize Dr. Jones's remark that certainly one of the most important phases in the removal of a cancer of this portion of the genito-enterologic tract is the adequate preparatory period, which has now become a rather routine custom in this country. I believe that some of the mortality from our colleagues of the continent would be avoided if they indulged in a little more preliminary preparation before operation was taken.

## MARRIAGE AMONG MENTAL DEFECTIVES

CHARLES P. SHELDON, M.D.

BOSTON  
AND

LLOYD H. ZIEGLER, M.D.

WAUWATOSA, WIS.

Among average or superior members of society, marriage presupposes adaptations and creates problems of a varied nature. It is difficult for all these to be satisfactorily resolved, even with every aid that can be brought to bear on them. In the case of handicapped persons who marry, the problems that ensue are no less numerous or complicated. But among the feeble-minded the awareness of such problems, by the nature of the circumstances, is relatively defective, and the burden of solution must be assumed largely by others in society more capable of bearing them.

This study was suggested by the admission of a woman to the public obstetric service of a large hospital. The facts pertaining to her are neither new nor unique. Doubtless similar persons can be found in any community. Her history follows:

*Hospitalization.*—Mrs. Q., a woman aged 20, was admitted to the indigent obstetric service June 19, 1935, at term, in her third pregnancy, which was normal. The children of two previous pregnancies had died soon after birth. Delivery of a male child weighing 7 pounds 14 ounces (3,573 Gm.) was spontaneous. The patient remained in the hospital fourteen days on a permit financed by the welfare department of the city. Her recovery was uneventful, except that it was noticed that she was uninterested in her environment and was unresponsive to instructions given by her attending physician for the care of herself and the baby. These features were so impressive that psychiatric consultation was obtained. The psychiatrist found that, according to the Stanford revision of the Simon-Binet intelligence test, her intellectual growth had been arrested when she was 7 years and 1 month old. Her basal mental age was in reality but 6 years. The intelligence quotient was 44. She did not know the meaning of Easter or the Fourth of July.

*Family.*—Such observations naturally aroused curiosity about her family. The patient's father had died of tuberculosis. Little more could be learned about him. The patient's mother, aged 51, lived with the patient and was usually dressed in filthy,

Read before the Section on Nervous and Mental Diseases at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

From the Department of Gynecology and Obstetrics and the Department of Neurology and Psychiatry of the Albany Hospital and the Albany Medical College, Albany, N. Y.

ragged clothes. Her intellectual growth had become arrested at 8 years 4 months, according to the Stanford revision of the Simon-Binet test. She had been married twice and had been pregnant nine times; six children survived. Two of these were the patient and her identical (monozygotic) twin sister, whose intellectual growth was arrested at 6 years 10 months. It was also said that none of the other four children could read or write or do more than simple labor at irregular intervals. By further investigation it was learned that the living conditions of the brothers and sisters were little if any better than those of the patient. Petty crimes had been committed by some members of the family.

**Past History.**—The patient's past history has been obscured by the absence of intelligent observation and potent memory. She had gone to school a short time but had not learned to read or write. She and her twin sister had had speech defects from an early age. The patient was legally married at 17 by a clergyman to the son of a junk collector whom she had known but a few days. The reason given for such a hasty marriage was that she wished to show her twin sister, who had married five days earlier, that she could "catch a feller, too." Her husband, about ten years her senior, was regarded as a shiftless, incompetent laborer, known to use liquor to excess. He had been the recipient of some form of public or private relief almost continuously since his marriage. He had been known to sell welfare food orders to buy liquor.

**Home Conditions.**—The visit of a social worker to the patient's home revealed almost unspeakable conditions. The family had moved frequently, being evicted for nonpayment of rent. At the time of the visit, several months after the patient had left the hospital, they were living in the poorest section of the city on the top floor of a very rundown three story frame house facing the railway tracks. The three room apartment was sparsely equipped with old and broken furniture; in fact, one room contained no furniture whatever. The rooms were filthy and disorderly. The floor was covered with ashes and sticks of wood. The only bed present had a soiled mattress and a grimy old blanket. Burlap sacks were used as pillows. The dining table was covered with old potato peelings. A few dishes and kitchen utensils were scattered about. The apartment was nearly as cold as the winter weather outdoors.

**Follow Up.**—The social service follow up of the patient and her family is a sordid tale of hardship and poverty. Her husband worked but little, becoming intoxicated whenever

Chart 1.—Distribution of patients according to their intelligence quotients.

possible, at which times he was cruel and quarrelsome. The entire family suffered from undernourishment, insufficient clothing and cold. The baby died at 7 months of age as a result of injuries sustained from inhumane treatment during a drinking debauch of its father.. The patient was four months pregnant at the time of the death of the child. The fourth child has since been born in the hospital, and the mother and baby are being observed in the free clinic. The needs of the family are met by the city welfare department. Between 1932 and 1936 the patient's family and her nearest relatives were granted in excess of \$9,000 for relief and hospitalization.

In perusing the records of the hospital it was not difficult to find many others in the files of the obstetric department not unlike that of Mrs. Q. This fact prompted the study of fifty unselected married patients seen in the free antepartum clinic over a period of about four months between July and October 1936. The Stanford revision of the Simon-Binet test was given to these patients by an experienced psychologist. The results of this study are recorded in chart 1 and

Chart 2.—Intercorrelation between age at marriage and intelligence quotient.

the table. The distribution of intelligence quotients approximates a normal curve in outline, suggesting random selection of the patients investigated. According to the tests, 22 per cent of these married women were feeble-minded, which is a far greater percentage than is to be found in the general population. In reality, they have participated in a form of child marriage, usually with governmental and religious sanction, that constitutes a more hazardous factor to society than the occasional child marriages so much publicized recently. And because of these marriages in our country, among persons imprisoned in a perpetual and unchanging childhood, it ill becomes us to cast the first stone at Mother India.

The intelligence quotients were plotted against age at marriage, as indicated in chart 2. This chart demonstrates, in general, that the lower the intelligence quotient the earlier they tended to marry.

In recent years the declining birth rate has attracted considerable attention. In order to learn something about pregnancy rates, the records of 964 obstetric patients who were delivered at the Albany Hospital in the years 1931-1935 were analyzed. Two hundred and sixty-two of these patients were confined in the maternity division supported by public funds. The remainder were able to pay for their own hospital care. The average number of months of exposure to pregnancy between pregnancies was 12.5 for the indigent group, in contradistinction to 22.4 for the self-supporting group, thus demonstrating a marked difference in the procreativeness of the two groups.

Perhaps of equal significance with birth rate is the survival rate of the children. In the case of the indigent group, the infant mortality was 94.6 per thousand live births, whereas for the self-supporting group it was 40.9. An analysis was made of the number of infants surviving the first year of life. A thousand pregnancies

in the indigent group produce 772 infants 1 year old, while a thousand pregnancies in the self-sustaining group produce 861 surviving infants. How well the children of these two groups may survive into the future is a problem, although it is known that the death rate among idiots and imbeciles is much higher than it is among normal people.

From such a survey we were led to consider the statutory impediments which the various states have enacted to prevent marriage among persons with outspoken arrests in psychic development. Such statutes vary enormously, as one would suspect, and include reference to psychoses and other diseases which are regarded as disqualifying for marriage.

The actual, or chronological, age of legal consent to marry is not uniform. The upper and lower age limits are 16 and 21 years for the female in Tennessee and Connecticut, respectively. There are modifications for these limits in all states to meet emergent obligations and to comply with the consent of guardians. Most states with

decrees prohibiting marriage among the feeble-minded provide for the withholding of the marriage license by the town or city clerk or other authorized person if he is aware that either party is legally incompetent to marry. In New York State a clerk who issues a license to marry to persons not competent, without first requiring them to make an affidavit showing that they are legally competent, shall be guilty of a misdemeanor. In the same state it is a misdemeanor to solemnize marriage if it is known that either of the parties is under the age of consent or is insane or an idiot, but the domestic relations law of New York permits the clergyman or officer, without such knowledge of legal incompetence, to solemnize matrimony legally once the license has been issued. In a number of states the applicant for a marriage license must make affidavit that he is free from the aforementioned defects.

In the District of Columbia and in nineteen states feeble-minded persons are not prohibited from marrying, although in some of these states the marriage may subsequently be declared void by judicial decree if one of the parties is an idiot or insane.<sup>1</sup> Twenty-nine of the states have laws attempting to cope with the problem. Perhaps the simplest is the Illinois law, which states that "no insane person or idiot shall be capable of contracting marriage." Massachusetts requires the certification of mental defect or disease in an institution to

1. Feeble-mindedness is very different from a psychosis, which may occur in persons of superior ability. Insanity is a legal term implying lack of responsibility sometimes associated with these disorders.

prohibit marriage. In Iowa the state board of control supplies quarterly to clerks of the court a list of such certified defectives who are disqualified for marriage. The clerk must refer to the list to be sure not to grant a license to a disqualified person. North Dakota requires an affidavit from a duly licensed physician showing that the contracting parties are not feeble-minded or otherwise disqualified. The North Carolina law defines the nature of the physician's duty in so certifying to the competence to marry, and false statement is a misdemeanor.

Many states prohibit clergymen or other officers from solemnizing marriage if it is known to them that either party is feeble-minded or has other disqualifying conditions. In Virginia any one having knowledge of such disqualifying attributes may appear before the clerk or clergyman and give reason why the marriage should not be consummated. In New Hampshire such questionable issues are referred to the state board of health.

Most states fail to acknowledge that marriage may entail the support of a family. In this respect the Indiana law (section 44-207) is unique and deserves being quoted:

No license to marry shall be issued where either of the contracting parties is an imbecile, epileptic, or of unsound mind, or under guardianship as a person of unsound mind, nor to a male person who is or has been within five years an inmate of any county asylum or home for indigent persons, unless it satisfactorily appears that the cause of such condition has been removed and that such male applicant is able to support a family and likely to so continue.

#### COMMENT

From our observations, and those of others, it seems clear that the feeble-minded above the grade of idiot may marry without much restraint even in states that have laws disqualifying them. The feeble-minded tend to marry earlier than normal adults and apparently they procreate more rapidly.

Our patient, Mrs. Q., was allowed to participate in a marriage contract without being sufficiently investigated. Her responsibility for entering into any kind of a contract is questionable. Her inability to care for herself, or even to learn to do so, is obvious. Her attempts to make a respectable home have been as feeble as her intellectual capacities. Children were born. Assuming that they were not feeble-minded on a hereditary basis, growth to adulthood in the environment which this mother provides would have a markedly adverse effect in fitting them to live in a cooperative community. On the other hand, if her children were feeble-minded—and this is the greater likelihood—they would perhaps suffer less harm from their home environment than those of normal intelligence but would nevertheless be deprived of the basic training and care so essential to the adaptations of the feeble-minded. It seemed natural for Mrs. Q.'s neighbors to be critical of her inadequacies. In the light of her definite arrest of psychic development, it is clear that her critics were neither understanding nor constructive in their condemnations.

One is impressed by the efforts of relief agencies who, with the best of intentions, pour out aid in such situations—firmly conditioned by incontrovertible facts—thus perpetuating them without much amelioration. This brings us to a consideration of the laws that have been intended to cope with such problems.

Unfortunately, law makers are not always biologists and therefore may not be sufficiently conversant with

conditions they aim to modify or control. Laws not infrequently mention idiocy (mental age 0 to 3 years) as a condition disqualifying for marriage. Few, if any, idiots are capable of attempting to contract marriage or to reproduce. Arrests of psychic development above this level (imbecility, with mental ages 3 to 7, and moronism, with mental ages 7 to 12) are frequently not mentioned in marriage-disqualifying laws. Most of such defectives are by nature incapable of, and irresponsible for, making contracts such as marriage. Since they often appear to be normal adults—but in reality are mere children—they are taken advantage of and exploited. In difficult times and in environments where they are not understood (and they usually are not) there is little recourse for many of them except in delinquency, relief rolls, or starvation.

Feeble-mindedness is a biologic condition, or state, with many possible causes. Heredity plays a considerable part in the transmission of this disease entity when it is not caused by injury or infection of the brain. It deserves to be classified with other diseases. It seems to be no minor defect in our marriage laws that they should in many instances be so worded as to place the responsibility for the recognition of this disease on a clerk, on a clergyman without medical training or on the defective himself. As a matter of fact, only a small percentage of physicians have had the training and experience to administer the tests by which feeble-mindedness above the very lowest grades may be recognized.

Governments have not attached sufficient importance to the age at which intellectual growth ceases; this is of much greater significance than the actual age of the person. If one examines the inmates of prisons, almshouses or reformatories, people on relief rolls or women who give birth to children out of wedlock, one finds that a far larger percentage of persons is included whose psychic arrest has occurred in childhood than is found in the population as a whole, in which the incidence of feeble-mindedness is about 4 per thousand inhabitants.

Sterilization has been advocated as a means of removing effectually the feeble-minded from the race. While students of the subject realize that the widespread use of this device can work but slowly, and perhaps ultimately ineffectually, nevertheless it may be applied to certain individuals to enable them to defend themselves from responsibilities which they are ill fitted to carry. A number of states have passed laws relating to the sterilization of defectives. In 1927 the United States Supreme Court upheld the validity of the Virginia sterilization law. Justice Holmes, in rendering the report, said:

We have seen more than once that the public welfare may call upon the best citizens for their lives. It would be strange if it could not call upon those who already sap the strength of the state for these lesser sacrifices, often not felt to be such by those concerned, in order to prevent our being swamped with incompetents. It is better for all the world, if instead of waiting to execute degenerate offspring for crime, or to let them starve for their imbecility, society can prevent those who are manifestly unfit from continuing their kind. The principle that sustains compulsory vaccination is broad enough to cover the cutting of the fallopian tubes. . . . Three generations of imbeciles are enough.

Segregation, with suitable vocational training, will do much to enrich the lives of some of these less fortunate people. At the same time, the social hazards of reproduction in this group can be eliminated. This

has never been adequately tried. If the costs of relief, dependence, delinquency and disease attributable to the feeble-minded could be transferred to the ledger on the side of wise segregation and training, not only would there likely be a definite and immediate pecuniary saving but there would also be future dividends of humanitarianism and prevention.

Compulsory registration of the feeble-minded is another way of attempting to deal with the problem. Reporting should be done to a central office, such as the department of mental hygiene or the department of health. Only those found by qualified examiners to have intelligence quotients of 70 or less should be registered. In this way the following of defectives and typhoid carriers would have much in common. Detection of persons with arrest of psychic development should begin in the public and private elementary schools. School officials could cooperate best by selecting for special study students who are retarded in their progress from grade to grade and those of school age who, by reason of their mental deficiency, have never been able to attend school. The wise utilization of knowledge about registrants might be vested in the authority of a commission having extensive knowledge and experience with such persons. Lists of registrants and consultation privileges with the special commission should be available to clerks and clergymen responsible for the licensure and solemnization of marriage. Under such circumstances, laws disqualifying the feeble-minded for marriage might be enforced more effectively. Courts should also have access to the same service. Too frequently courts sentence offenders in accordance with a legally specified prison term when, in reality, an unchangeable biologic condition exists, unameliorated by prison experience; from such persons the safety of society requires perpetual segregation. No single plan, or any combination of several methods, can be perfect. Such a commission, however, could utilize registration, wise guidance and supervision, sterilization and segregation, depending on the situation, in the most practical ways to discourage or prevent reproduction and antisocial living.

The expenditures incurred in the United States by allowing the feeble-minded to live as they wish, with palliative assistance, has perhaps been one of the heavy prices we have paid for what we call personal freedom. We are at the threshold of a reappraisal of the liabilities and the assets involved which can come about through a broadened interest in the public health. If individual liberty is lost when one has smallpox or leprosy, it would seem that the chronic disease feeble-mindedness might be controlled in the interest not only of the patients themselves but for the health, economy and safety of the public as well.

270 Commonwealth Avenue—1220 Dewey Avenue.

#### ABSTRACT OF DISCUSSION

DR. DWIGHT L. WILBUR, San Francisco: The authors have raised some questions with regard to problems which will vitally affect our future. I agree that further study should be made of the problem of marriage among those who are mentally defective with the idea of reappraising the liabilities and assets of such marriages to the public health. There is still much controversy with regard to the influence of heredity on the mental equipment of the offspring and with regard to the effectiveness of sterilization of mentally defective persons in controlling the incidence of mental deficiencies. Since the problem has legal and sociologic implications, it seems that it would be wise to have more data available before addressing methods of

control of this problem to the courts and to sociologists and social workers. It should be recalled how difficult it has been to obtain enforcement by legal means and acceptance by the public of such well established methods of public health control as vaccination to prevent smallpox and as antitoxin in the prevention and treatment of diphtheria. Of equal importance to a study of the effect of hereditary influences and of sterilization in the control of feeble-mindedness and of other types of mental deficiency is a study of the influence of environment on the offspring of normal and of mentally defective persons. Such a study should be made before a definite policy is established with regard to the methods of dealing with this problem. Until further studies of the effect of heredity and environment on the development of mentally abnormal persons are available and lead to fairly definite conclusions, it would be wise for us to assume a rather conservative attitude in adopting an aggressive policy with regard to the best method of handling the problem of marriage among mentally defective persons.

DR. LAWRENCE KOLB, Lexington, Ky.: The authors are to be commended for bringing to attention in a striking way the folly and danger of unrestricted breeding of the unfit. It has become the fashion these days to scoff at measures designed to improve the race or to prevent its deterioration. The statistically minded tell us that if all the feeble-minded were sterilized there would be no definite decrease in the total number in the next generation, and unfounded statements are made that if eugenicists had had their way such and such a genius would never have been born. Breeding psychopaths and other defectives on the chance that one of them might turn out to be a genius is much like sowing weeds in a corn field with the hope that one may bloom into a beautiful flower. In any event, whatever might be said for the psychopath as a source of genius surely does not apply to the feeble-minded. The authors show that 22 per cent of their indigent groups of pregnant women were mentally defective according to accepted methods of testing, that the lower the intelligence quotient the earlier they tend to marry, and that the birth rate among the indigent is higher than among self-supporting more intelligent groups. We may rest assured that the innate selfishness common to all groups will prompt the more intelligent to disregard the unfavorable birth trend so far as it applies to their own personal convenience, while the morons, through unintelligent indifference to anything but animal needs, will continue to breed at a high rate. The remedy then lies in some positive action by the intelligent group. A start has been made through the medium of certain state laws, but these laws are, as a rule, ineffective, owing in part to the indifference or lack of sympathy of the public. The public must be aroused to the dangers in the present situation and the possibilities of improving it through measures that will take account of the defects inherent in intelligence testing and which will not interfere with the normal sexual urges of any one. The authors have given a broad outline of how the problem should be approached, but the public must be further educated before adequate remedies can be applied.

DR. FRED O. BUTLER, Eldridge, Calif.: Our experience in California is worthy of mention at this time. Perhaps some are not aware of the extent of sterilization that has been done in California, especially at Pacific Colony and Sonoma State Home, the two institutions for defectives in this state. We have sterilized to date over 12,000 mentally defective and insane, over 3,300 of this number at the Sonoma State Home, and of this number about 400 are married and getting along satisfactorily. We feel that without sterilization our marriages would not be so successful, when it is considered that they come from families with as many as twenty-three defectives in one family and the next largest family having seventeen defectives, both parents also being defective and likewise the grandparents. We have several of three generations in our institution and only one instance in which the offspring of these defective parents has been brighter than the parents, the majority of them having been far lower mentally than the parents. The average intelligence quotient of those married is about 60. Their marriages are about 100 per cent more successful than the marriages among the group presented here today, partly because of the careful investigating and the approving of the marriages. I feel that we do this more thoroughly than is done by the average

normal parents with their own sons and daughters because we feel a responsibility in allowing these boys and girls to marry. We ascribe our success to thorough investigation by the psychiatric social service department and keeping them under close supervision for about two years. Many of them have their own homes and they fit into communities far better than many so-called normal people. This could not, of course, be done so successfully without the operation for sterilization, which prevents a burdensome family on their hands. We have many come into our institution, the family having been broken up on account of their inability to care for their children.

## CANCER OF THE LARYNX

CHEVALIER JACKSON, M.D.

AND

CHEVALIER L. JACKSON, M.D.

PHILADELPHIA

The literature of malignant disease of the larynx is so voluminous that any presentation should have a bearing only on the as yet inconclusively determined phases of the subject, especially those that seem to call for revision of opinion.

We have therefore analyzed our data with a view to determining what light they throw on the following questions:

1. Is the physician justified in limiting the use of irradiation to cases in which operation is contraindicated?
2. Where shall the line be drawn between cases for operation and cases for irradiation?
3. What is the bearing of the degree of malignancy on the choice between operation and irradiation?
4. Is it justifiable to do a laryngectomy for a small growth in the anterior commissure even if the degree of malignancy is high?
5. In view of the later improvements in the technic of irradiation is the surgeon not justified in doing fewer laryngectomies?

### 1. IS THE PHYSICIAN JUSTIFIED IN LIMITING THE USE OF IRRADIATION TO CASES IN WHICH OPERATION IS CONTRAINDICATED?

Our statistics show that up to the year 1930 the results of irradiation were so disappointing that, unquestionably, no patient with a growth of the class regarded as operable should have taken the practically hopeless chance of even relative cure by irradiation. Since the year 1930, however, our observations have led us to believe that there are growths classed as operable for which the patient is justified in choosing irradiation in preference to operation. The year 1930 was selected as the dividing line somewhat arbitrarily for convenience in studying our statistics. It should not be inferred that there was an abrupt change in our results or our opinion. In fact there is so much overlapping in the clinical evidence that a dividing line could not be clearly determined, and the evidence does not yet warrant a conclusive opinion. But the contrast afforded by the grouping of cases observed before and after the date mentioned has yielded a basis for present guidance in selecting the form of treatment that seems best for each particular patient.

Our statistics do not as yet justify abandonment of the well established operation of laryngofissure when the

Read before the Section on Laryngology, Otology and Rhinology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

growth is operable by this method. By operable growth in this connection we mean early intrinsic cancer of limited extent.

On the other hand, when the malignant growth is locally ideal for operation but the patient is a bleeder or has a serious organic ailment such as marked arteriosclerosis, advanced cardiac disease, intractable diabetes, pulmonary tuberculosis, a psychosis, or any other condition abnormally shortening life expectancy, we would now class the patient as unsuitable for operation whereas formerly we would have advised operation. In other words, though we still feel that we should limit irradiation to the class of patients unsuitable for operation, classification of patients has been somewhat changed by the improved results obtainable by irradiation and we now classify as unsuitable for operation a somewhat larger proportion of patients with early intrinsic disease.

Table 2 shows data from our records bearing on the question of irradiation in the treatment of cancer of the larynx.

Terminal records are incomplete. So far as can now be determined no patient survived a year after the

beginning of the irradiation. All the patients were deemed unsuitable for operation for local or general reasons. Three patients with positive serologic reactions had energetic antisyphilitic treatment before irradiation was begun. Many of the patients in this series were seen in consultation and were not followed through the treatment.

The results of irradiation in the foregoing series of cases were so discouraging that they were regarded as justifying advice against irradiation even when the growth is inoperable. Radiation as then applied if used in sufficient strength to get any effect seemed to hasten rather than retard a fatal termination. It should be stated, however, that in many of the cases metastases had rendered the prognosis utterly hopeless before irradiation was used.

In 1930 and the two subsequent years unquestionable evidence of better results from irradiation, especially the results from the use of radium in the hands of Dr. George E. Pfahler, convinced us that improved technic rendered irradiation advisable in all cases in which the cancer was inoperable and there was no evidence of pulmonary metastases or general carcinomatosis.

Then came the technic of irradiation with the roentgen ray devised by Coutard. The results of the application of the roentgen ray and of radium by the newer technics have been so good that we have since advised

irradiation in all cases in which the cancer is inoperable, but we have left to the judgment of the radiologist in charge the choice between the use of radium, of the roentgen ray and of the two combined. In the cases reported in our records irradiation has been performed by Drs. M. C. Cameron, Russell H. Boggs, William S. Newcomet, George E. Pfahler, Henry K. Pancoast.

W. Edward Chamberlain, Eugene Prendergrass, Willis F. Manges, John T. Farrell, Karl Kornblum, Leon Solis-Cohen, J. Gershon Cohen and their associates.

Complete data on all the patients subjected to irradiation since 1930 will be published later. During this period excellent results were obtained in a number of cases by Dr. W. Edward Chamberlain using a modified Coutard technic:

The patient receives 125 roentgens daily to each side of the larynx for twenty-five treatments, a skin portal from 7 to 10 cm. in diameter and a skin target distance of 50 cm. being used. With the factors 180 kilovolts (average), 8 milliamperes and a filtration of 2 mm. of copper plus 1 mm. of aluminum, 10.6 roentgens a minute is delivered to the skin, the time being 11.8 minutes to each side. The total dose is 3,000 roentgens or slightly more to each side.

The data shown in table 3 seem to justify our decision in favor of irradiation, at least for cases in which the cancer is inoperable.

Patient living, free from recurrence after 3 years.....	4

The cancer in all cases was deemed inoperable because of (a) extent of the lesion, (b) adenopathy, (c) extrinsic location or (d) involvement of the posterior portion of the tongue. Considering the unfavorable character of the lesions, the results are remarkable.

In answer to the question Is the physician justified in limiting the use of irradiation to cases in which operation is contraindicated? we may say that deduction from our statistics has led us to believe that he is scarcely so justified, but we still believe that, for the present, laryngofissure should be preferred to irradiation in cases of early intrinsic cancer. We believe also

that there are cases in which total laryngectomy may still be regarded as the treatment of choice. The indications for laryngectomy have recently been very clearly stated by Schall,<sup>1</sup> who has also shown convincing proof of the excellent psychic and social adjustment made by most of the patients despite the mutilating and crippling character of the operation.

## 2. WHERE SHALL THE LINE BE DRAWN BETWEEN CASES FOR OPERATION AND CASES FOR IRRADIATION?

Fundamental to the consideration of the choice between operation and irradiation is a clear statement of what is meant by operation. There are four classes of operation, each so different as to both the operative risk and the after-condition of the patient that to take all four classes as one method for comparison with irradiation would be very misleading. We shall therefore consider (a) endoscopic operation, (b) laryngofissure, (c) laryngectomy and (d) lateral pharyngotomy.

With both endoscopic operation and laryngofissure the operative risk is negligible and the after-condition

three recurrences. Kernan's conclusion is the same as ours, that while endoscopic removal is possible it is not to be recommended.

The tip of the epiglottis is the only part of the extrinsic area that, according to our experience, is amenable to operation, and this in only one class of case.

Nowhere in the body is there a greater contrast between the early and the late stages than in the epiglottis. Though our cases of cancer in the early stage were few, they show that a small and extremely early carcinoma located at the center of the tip of the epiglottis is, for a time at least, a strictly local process so amenable to surgical treatment that direct laryngoscopic extirpation can be curative. By way of contrast, a lesion that has started or has extended slightly downward becomes one of the most fatal of all carcinomas of the larynx, because of leakage into the base of the tongue.

New<sup>3</sup> has on several occasions, notably in a cancer symposium at the Clinical Congress of the College of

TABLE 4.—Cancer of the Epiglottis

of the patient is practically normal. With both laryngectomy and lateral pharyngotomy the operative risk must be considered and the after-condition of the patient is one of mutilation and economic disability. These disadvantages do not mean that these operations are inadvisable, but the distinctions are essential to an unprejudiced consideration of the choice between operative and irradiative treatment.

**Endoscopic Operation.**—We have seen a number of instances in which removal of material for biopsy had so completely removed the growth that no evidence of a malignant process could be found in the mass of basal tissue removed at subsequent laryngofissure. This, however, has not led us to feel justified in endoscopic excision except in certain cases of epiglottic cancer.

Kernan<sup>2</sup> stated in a recent paper that he had had two cases in which the tumor had been completely removed endoscopically when tissue was taken for biopsy. In one of his cases no further procedure was done; in the other the cord was removed by laryngofissure. In neither case was there a recurrence. According to Kernan, Lynch had reported nine cases of endoscopic removal of a laryngeal carcinoma with

Surgeons, held in San Francisco three years ago, advocated the extirpation of small tumors of the epiglottis of low grade malignancy by surgical diathermy under suspension laryngoscopy. Tucker<sup>4</sup> has reported cases of epiglottic tumor in which he removed the involved epiglottis by the laryngofissure route.

In view of the foregoing facts, we may say that our clinical experience seems to indicate that in the case of cancer of the epiglottis the line between operation and irradiation is to be drawn between the small, extremely early lesion located centrally on the tip, which is an operable lesion, and a growth below the margin by origin or extension, which is of questionable operability. For all growths of the latter class irradiation is our first choice.

**Laryngofissure.**—For a small, early growth located within the intrinsic area in a patient otherwise free from organic disease we would not feel justified in advising anything other than laryngofissure. On the other hand, for a patient with such a growth whose life expectancy is seriously shortened by diabetes, pulmonary tuberculosis, cardiovascular disease or other organic disease we would advise irradiation. It cannot

be too strongly stated, however, that this preference for irradiation is not due to any operative risk; not one of the conditions mentioned, in a properly prepared patient, is a contraindication to laryngofissure. The preference is based on the fact that irradiation has now reached a degree of efficacy that renders it probable that the patient will live out his short expectancy without recurrence after irradiative arrest. The extent to which the conditions mentioned are to be regarded as contraindications to irradiation must be decided in the particular case.

Of all the cases of malignant disease of the larynx in which laryngofissure was performed prior to 1930 there are 111 that are sufficiently complete as to details to be worth analysis. These cases are divided into two groups for the purpose of determining the curability of malignant disease of the larynx by laryngofissure in cases suitable for this procedure. The question that immediately arises is Why do the operation in unsuitable cases? The reason is that when, in the days when irradiation was so disappointing, a patient with a cancer that was not ideal for laryngofissure refused to have a laryngectomy done, laryngofissure was the alternative. The responsibility was placed entirely on the patient. If, after full explanation of the increased risk of recurrence, the patient insisted on taking the increased risk rather than lose his larynx, it seemed inhuman to refuse to try to help him. A number of the patients were physicians. Under such circumstances it was deemed proper to do laryngofissure, but it would seem improper to include these cases in a group analyzed for the special purpose of determining the curability of cancer of the larynx by the laryngofissure route in suitable cases. This grouping enables the surgeon to tell future patients what the chances are in the class of case to which they belong. In no instance was laryngofissure done for advanced or extrinsic cancer when there was no hope of adequate removal. It may here be stated parenthetically that this situation is handled better today by advising patients who are not ideal subjects for laryngofissure (group A) to be treated with irradiation if they refuse consent to laryngectomy.

Fig. 1.—Small early cancer of the left cord, as seen reversed in the mirror. In this stage cancer is curable in 82 per cent of the cases, but unfortunately in all but 19 per cent it is overlooked. The only symptom is slight hoarseness, usually intermittent. Frequent or persistent hoarseness in an adult should be regarded as of cancerous origin until proved otherwise by proper diagnostic methods. Total laryngectomy would be a rare operation if all intrinsic laryngeal cancers were discovered in this stage.

In table 5 are included some cases (group A) in which laryngofissure was done although we had urged laryngectomy as preferable; the patient refused the latter and preferred to take the greater chance of recurrence involved in a laryngofissure for a lesion too extensive for best chances of success by this procedure. These cases are included here for completeness but should not be taken as criteria of the adequacy of laryngofissure in suitable cases. They were eliminated for this reason in a selected series of cases presented as part of the "Cancer Is Curable" symposium arranged by the late Franklin Martin.<sup>5</sup>

Insufficient time has elapsed for us to report finally on the results obtained in patients operated on since 1930, but it may be said that, of forty patients in whom

laryngofissure was done between 1930 and 1934, thirty-four, or 85 per cent, were free from recurrence three years after operation. This series includes all patients in whom this operation was done during the aforementioned period except one who died of cardiac disease before the lapse of three years. Several of the cases would be in the "unsuitable" group if such a division as was made in the tabulation of the cases in which operation was performed prior to 1930 were made in this series.

**Laryngectomy.**—As between laryngectomy and irradiation we are decreasing the number of laryngectomies in proportion to the number of patients treated with irradiation. We find irradiation better for many patients for whom a very few years ago we would have advised laryngectomy.

One class of case stands out sharply and clearly in our minds, namely that in which life expectancy is shortened by organic conditions independent of the laryngeal cancer. In such cases, it seems to us, irradiation should be used. Total laryngectomy should be reserved for the well preserved patient with a good vascular system for his years who is organically sound. There are some patients in whom no organic disease can be found who are nevertheless poor operative risks. We feel that the surgeon should beware especially of the patient who acknowledges "moderate drinking." Usually this admission means that, though perhaps rarely intoxicated, the patient drinks steadily all the time he is awake. For seventeen or eighteen hours out of each twenty-four his capillaries are dilated, his heart accelerated and his mental activity goaded. Such a patient, though not to be classed as an alcoholic addict, is a poor subject for laryngectomy. With a cancer of the larynx locally beyond the limit of laryngofissure yet still intrinsic, he will do better, on the average, with irradiation rather than with laryngectomy.

Table 6 presents data concerning the cases in which laryngectomy was done prior to 1930. In considering the rather high operative mortality one should make due allowance for the lack of the then undeveloped knowledge of diabetic control, edentulous preparation and other factors that increased the risks of major operations. Many of the operations were in cases of extensive local and metastatic lesions that would today in our opinion be classed as unsuitable for operation in the sense that operation is hopeless and irradiation hopeful. It should be noted that in only eighteen of the entire ninety-five cases the cancer was definitely intrinsic. Moreover, though degrees of malignant aggressiveness were recognized clinically,<sup>6</sup> pathologists had not developed the technic of

Fig. 2.—The overhanging epiglottis concealed from mirror view until late a cancer that started on the anterior end of the left cord. Visualization of the anterior commissure in all adults is necessary if cancer is to be detected in the curable stage. This visualization can be done in every patient with the direct laryngoscope.

Fig. 3.—Leukoplakia of the larynx. In the larynx as elsewhere on mucosal surfaces, leukoplakia is potentially precancerous and should be extirpated.

preoperative determination from biopsy specimens. The aggressiveness shown by the clinical progress of many of the patients indicates that a considerable number of them would not have been operated on under our criteria of today.

TABLE 5.—*Patients with Malignant Growths of the Larynx Operated on by the Laryngofissure Route Prior to 1930*

Group A: Laryngofissure (patient's choice) in cases not strictly suited to this procedure.....	51

should encourage them to continue their efforts. There is no question as to the accessibility of the back wall of the larynx by this route, but our own early results were so discouraging and the recent results of irradiation have seemed so surprisingly good by comparison that we at present place party wall laryngeal cancers in the extrinsic class, for which irradiation is preferable to operation.

### 3. WHAT IS THE BEARING OF THE DEGREE OF MALIGNANCY ON THE CHOICE BETWEEN OPERATION AND IRRADIATION?

The question of the bearing of the degree of malignancy on the choice between operation and irradiation is of fundamental importance. It can, we believe, be answered definitely enough as to operation, but the question of irradiation is so interlocked with the matter of the relative radiosensitivity of the four types of malignant process now accepted by pathologists that, for the present at least, the decision must rest with the radiologist and the pathologist consulted in the particular case.

On the operative phase of the subject we may say that our experience has convinced us that the degree of aggressiveness in the particular case is of primary importance. Many years ago one of us pointed out the great variation in degrees of malignancy and its bearing on the results,<sup>6</sup> but until the formulation of histologic types by Broders we had no guiding criteria. Since our histologists have systematically typed our biopsy speci-

mens we have based certain decisions as to choice of treatment on their reports.<sup>7</sup> Most of our clinical work in recent years has been based on the grading of Dr. Frank W. Konzelmann. There may in some cases be a variation in the histologic picture in different parts of a cancer; therefore for typing it is important that the histologist have an ample specimen. In the case of large growths we believe it best to take a specimen from two or more locations; in the case of small growths it is well to remove the entire tumor.

A number of years must elapse before definite rules can be laid down, but our experience so far has led us to formulate a general outline as follows:

(a) We deem laryngofissure advisable for every small early growth anywhere in the intrinsic area in a patient free from general organic disease regardless of the degree of malignant aggressiveness.

(b) For an advanced but still intrinsic growth of grade 1 or 2 in a patient free from other organic disease we would advise laryngectomy, but we would deem irradiation preferable for cancer of grade 3 or 4.

(c) For intrinsic growths with glandular metastases we deem irradiation preferable regardless of grading.

(d) In a general way it may be said that extrinsic growths are less amenable to operation and more amenable to irradiation as compared with intrinsic lesions. We are inclined at present to regard tumors of grade 4 as more sensitive but yielding results less permanent as compared with tumors of grade 1. Grades 2 and 3 are relatively similar but less sharply contrasted.

4. IS IT JUSTIFIABLE TO DO A LARYNGECTOMY FOR A SMALL MALIGNANT GROWTH IN THE ANTERIOR COMMISSURE?

It is universally accepted among surgeons that it is best, in dealing with a malignant tumor anywhere, to remove the growth with an adequate area of surrounding normal tissue without cutting into the neoplastic tissue.

The only question to be determined then, in the case of laryngeal cancer, is whether or not this can be done without extirpating the whole larynx. If the ordinary technic of laryngofissure is followed the clipping of the cartilage will certainly go right through a growth in the anterior commissure. This deplorable procedure can be entirely avoided in the case of small growths by the special anterior commissure technic which has been in use in our clinic twenty-one years.<sup>8</sup> Until three years ago this operation had been done for a small

In answer to the question Is it justifiable to do a laryngectomy for a small malignant growth in the anterior commissure? we may say that in our opinion this procedure is perfectly justifiable and proper if the surgeon's experience leads him to believe that in performing it he is acting for the best interest of the patient. In our own work, however, since the development of the anterior commissure operation, we have found that it is not necessary to sacrifice the whole larynx in such cases. It should be stated that before doing the anterior commissure operation we make certain in each case that the growth is small. Certainty is the result of systematic preoperative examination. Furthermore, we pay particular attention to the grade of malignancy in deciding between laryngofissure and laryngectomy and between operation and irradiation.

Before doing any operation for cancer of the larynx we wish to know the extent of the growth, the location

growth in the anterior commissure in forty-two cases, and of these thirty-four were traceable. Table 7 is a summary of the results.

Operative technic is not within the scope of this article, but there are two points that seem to require mention because they may have had a bearing on the results obtained and because, though described many years ago, they seem to have been ignored by writers and operators. One is the value of the anterior commissure operation described. The other is the rule that skin flaps should not be made and the larynx should not be even partially skeletonized in laryngofissure. The line of incision in the skin should be carried down to the cartilage layer by layer without any separate retraction. The abundance of soft tissue with vessels intact, undetached from the external perichondrium, preserves the vitality of the external perichondrium and thus prevents necrosis of the thyroid cartilage.

8. Jackson, Chevalier: The Results of Operative Methods in the Treatment of Cancer of the Larynx, Symposium, Ann. d. mal. de l'oreille, du larynx 41: 1221-1239, 1922.

of its lower border and whether or not there is evidence of leakage out of the laryngeal box. We feel it quite unnecessary for the surgeon to be so often astonished to find at operation a large extent of subglottic growth or an enlarged lymph node over the cricothyroid membrane. Both of these conditions can easily be and, we think, should be determined by preoperative examination. This consists of three procedures: direct laryngoscopic examination, external palpation and roentgen examination of the neck.

Before deciding to do an anterior commissure operation it is necessary to know that the growth really is small. Only too often what looks in the mirror like a small growth is found on direct laryngoscopic examination to be so extensive as to exclude all hope of adequate removal by laryngofissure. To do the anterior commissure operation would certainly be disappointing; the ordinary clipping laryngofissure would be worse still. This deplorable pitfall is entirely avoidable. The exact size of the growth and the precise location of its

lower border can almost always be determined by direct laryngoscopic examination of the subglottic region, and this is the only way in which the determination can be made beforehand. The best instrument for this examination is the rotating laryngoscope, though most of our work has been done with the standard anterior commissure form. In many cases what appears in the mirror to be a small growth at the anterior commissure is found to be a large subglottic lesion extending downward to the cricothyroid membrane, which always suggests possible leakage out into the soft tissues of the neck through the cricothyroid membrane or even between the cricoid and thyroid cartilages. Whether or not such leakage has occurred can often be determined by delicate palpation.

When we speak of the palpation of the larynx we do not refer to the routine, and of course necessary, surgical search for lymph nodes in the neck. We mean a careful and delicate outlining of all the laryngeal cartilages with the palpatory surface of the index finger trained to the contour of the normal. Any filling in or firmness of the normal slight depression between the thyroid and cricoid cartilages is a warning of probable leakage. The next step is to palpate every square centimeter of the cartilages for tenderness; if any tenderness is found, perichondritis is probable and any operation is contraindicated. Then a careful palpation of the region of the cricothyroid membrane is made for that little lymph node whose presence is so often a surprise at operation. It can always be detected at preoperative examination unless the neck is very fat. Of course the enlarged node found at operation may not show histologic evidence of carcinomatous metastasis, but we believe that the clinician is justified in advising against laryngofissure in most cases in which an enlarged gland has been found at preoperative examination.

The lateral roentgenogram is often valuable as a graphic representation of a laryngeal growth. It is of especial value when infiltration of the anterior subglottic region causes resistance to the direct laryngoscope. In such cases the process is beautifully delineated by the injection of a few cubic centimeters of iodized oil.<sup>9</sup> When this degree of infiltration is present the anterior commissure operation or any operation by the laryngofissure route is contraindicated.

##### 5. IN VIEW OF THE LATER IMPROVEMENTS IN THE TECHNIC OF IRRADIATION IS THE SURGEON NOT JUSTIFIED IN DOING FEWER LARYNGECTOMIES?

Elapsed time is not yet available in many of our cases because of the recency of development of the Coutard technic of roentgen irradiation and of the most efficient use of radium, but our experience is sufficient to warrant the belief that the future will probably see a progressive decrease in the relative number of laryngectomies.

One obvious reason for this is that, whereas formerly the surgeon was justified in taking desperate chances by laryngectomy when the patient's general expectancy was short, because of the 100 per cent mortality without treatment, the greatly increased efficiency of irradiation indicates that laryngectomy should now be limited to good surgical subjects of good general expectancy.

## ABSTRACT OF DISCUSSION

DR. MAX CUTLER, Chicago: The paper presented by the Jacksons is both valuable and comprehensive. The question of surgical intervention and irradiation in the treatment of carcinomas of the larynx involves three types of tumors: 1. Large, extensive, inoperable, extrinsic carcinomas of the larynx, which are outside the domain of surgical treatment but which, as a rule, are composed of highly undifferentiated cells and are radio-sensitive, require no discussion, as they are admittedly inoperable both technically and biologically. 2. At the other extreme are small carcinomas limited to the true vocal cord, which are technically operable. When biopsy discloses an adult hornifying squamous type and the lesion has not reached the anterior commissure, surgical removal gives excellent results and is the method of choice. About 20 per cent of the lesions, however, affect the true vocal cord and are technically operable but biologically inoperable. In spite of their small size and technical operability, they are composed of undifferentiated cells which have extended along the lymphatics anteriorly to the commissure or posteriorly to the arytenoid process. Surgical removal is commonly followed by local recurrence, and the surgeon is surprised to find a local recurrence after the removal of a lesion which seemed so favorable and so definitely operable. Such lesions are radiosensitive and respond well to radiation therapy. It would be interesting if, in surgical statistics, they were segregated and an attempt made to determine whether the failures do not occur when the tumor exhibits this structure. Perhaps the 20 per cent would respond better to irradiation. There are no statistics on irradiation, however, to support this thesis. 3. There exists an intermediate type, with which a decision between surgical treatment and irradiation is difficult. The difficulty may be due to the lesion's being of borderline operability or to the patient's age or his general condition, which may contraindicate operation. The individual factors in each case must be carefully considered. These factors are histologic and clinical. Histologically, if the tumor is highly undifferentiated, it is generally radiosensitive. If it is of an adult squamous form, it is generally radioresistant. A more accurate guide to radiosensitivity, however, is the fixation or mobility of the cord. The highly undifferentiated tumors are almost without exception movable even when they are extensive. The differentiated types are nearly always fixed. When a discrepancy exists between the structure and the mobility of the parts, the latter is the more reliable sign. It is important to recognize that fixation may be due not to neoplasia alone but also to inflammation. A moderate amount of irradiation invariably results in reestablishment of mobility when fixation is due to inflammation.

DR. SIMON JESBERG, Los Angeles: In 1931 Coutard presented his results covering a ten year period of treatment of laryngeal cancer by irradiation. Previously operation was considered the only hope for cure of this disease, at least in the United States. Surgical treatment has since been replaced more and more by irradiation. Selection of type of treatment is the important problem confronting the surgeon today. The bad results of a few years back have been much lessened by improved technic in irradiation, and the indications for surgical intervention have been curtailed as a consequence. Entire removal or destruction of a cancer is essential for a cure. Whatever method is selected, the good and the bad end results must be considered. Many factors besides the actual pathologic conditions, such as the age, occupation, physical and psychic status and economic position of the patient must be considered. For example, a radio announcer aged 42 had a small grade 3 squamous cell carcinoma just above the arytenoid process. Loss of voice would have been an economic catastrophe. Laryngofissure did not offer much chance for cure. As a result of irradiation he has a good voice and is able to keep his position. After three years there has been no recurrence. Slight dryness and huskiness of the voice are his only complaints. If he had had a neoplasm of a low degree of malignancy, the irradiation required would have given a much worse end result and probably less chance of cure than surgical intervention. As the efficiency of irradiation is developed there will be fewer operations. It is only by the study of such a large series as the authors' that one can

9. Jackson, Chevalier L.: The Value of Roentgenography of the Neck with Special Reference to Its Use in the Diagnosis and Treatment of Laryngeal and Tracheal Obstruction, *Ann. Otol., Rhin. & Laryng.* 45: 951 (Dec.) 1936.

learn to select the treatment intelligently. For a very small tumor of a high grade of malignancy in the anterior commissure, I would recommend surgical removal by laryngofissure followed by irradiation.

DR. JOSEPH C. BECK, Chicago: I am sorry Professor Coutard is not here to defend his side of the radiologic question. There should be in this discussion a "radiumologist" and a radiologist, because, as Dr. Jesberg said and as the Jacksons' paper would indicate, we have not yet reached the point where we can speak definitely. I have great hopes for the effect of proper irradiation carried out by experts on cancer, because I have seen excellent results in the treatment of certain kinds of tumors of the larynx. I would say that the results depended on whether the tumor was radiosensitive or radioresistant. However, in association with Dr. Cutler in one of the largest institutions for the care of carcinoma of the larynx, namely the Veterans Administration Facility at Hines, Ill., I have seen similar results in the case of radioresistant tumors that were really operative and yet were subjected to irradiation at the patient's request. Recently Dr. Schall painted an excellent picture of laryngectomized patients and said truly that they are not a great unhappy family, as they are so often described. Most of the people who are cured of cancer of the larynx are glad that they are permitted to live on with an educated or artificial voice. If they become dependents now, since so many people are dependents they don't have to care so much about that. Most laryngectomized patients do become dependents, according to my experience. They are not productive, especially if they are salesmen. I am definitely at variance with Professor Coutard about making the fixed cord which is immovable from inflammation move again. I have not seen this happen. The inflammation is chronic and is not, according to radiologists, affected by irradiation. I do not think it should be considered in the prognosis. Dr. Jesberg also was definitely wrong when he said that for a tumor which was very sensitive to irradiation he would operate. I have seen the worst kind of results from such a procedure, namely rapid spread not only into the glands of the neck but throughout the system. The surgeon should be much more alert to the pathologist's decision as to what type tumor he is treating.

DR. CHEVALIER L. JACKSON, Philadelphia: I appreciated very much hearing Dr. Cutler's discussion. Dr. Jesberg and Dr. Beck have both spoken about lesions of the anterior commissure. We feel that it is much more important to consider the histologic picture with such lesions than with lesions in the middle third of the cord. It is with lesions of the anterior commissure that the final decision will depend on the histologic picture. The highly malignant lesion will certainly not be suitable for operation, but the lesion of low grade malignancy will be operable, and very successfully so, even if it does involve the anterior commissure. One of our tables lists thirty-four cases of lesions of the anterior commissure in which laryngofissure was done by the Chevalier Jackson anterior commissure technic. In this operation introduced by Dr. Chevalier Jackson in 1922, we divide the thyroid cartilage from the outside with a saw instead of clipping through the lesion with shears. Of our series of thirty-four patients, twenty-seven, or 79 per cent, were free from recurrence for three years. The last thing I wish to say is with regard to movement of the cord, a point which Dr. Beck mentioned. I have frequently seen irradiation restore the motion of a fixed cord whether the immovability was due to neoplastic infiltration or to inflammation.

**Muscle Physiology.**—Several observations by Bernard foreshadow the intensive work of the last decade in the field of muscle physiology. He found that blood leaving a contracted muscle is more venous than that leaving the same muscle at rest, i. e., although a living muscle always consumes oxygen, the consumption is increased during activity; and there is an accompanying increase in heat production. But if the motor nerve to the muscle is cut, there is very little oxygen consumed, even less than in a normal inactive muscle. This shows that, while the constant nerve impulses which keep the muscle in a state of semiactivity which we call *tonus* cause the muscle to consume a certain amount of oxygen, active contraction causes it to consume still more.—Olmsted, J. M. D.: Claude Bernard, Physiologist, New York, Harper & Bros., 1938.

## NEW STUDIES IN SURGICAL BACTERIOLOGY AND SURGICAL TECHNIC

WITH SPECIAL REFERENCE TO DISINFECTION  
OF THE SKIN

PHILIP B. PRICE, M.D.

BALTIMORE

Surgical technic has from the first suffered the lack of a quantitative test for degree of disinfection of the skin. It has been impossible to determine the precise effect of any hand disinfectant or stronger cutaneous germicide because the size of the bacterial flora could not be measured either before or after employment of the agent. In consequence there is a tremendous literature on the subject but little unanimity of opinion or uniformity in practice.

### A NEW QUANTITATIVE METHOD OF STUDYING THE BACTERIA OF THE SKIN

If a large number of basins of sterile water are prepared and the hands and forearms are scrubbed with soap and brush in a standard manner for exactly one minute in each basin, one after another, the washings will be found to contain a slowly diminishing number of bacteria. The cumulative totals plotted against time produce a curve. This is found to be a regular, logarithmic curve that is constant. From a study of this curve the size of the flora of the scrubbed area can be determined accurately.

Furthermore, by employing two such series of basins and plotting the two curves independently, the germicidal effect of any disinfectant used in the interval may be studied quantitatively. This introduces a new scale of germicidal value—the measured action of germicides in reducing the bacterial flora of skin as compared with the effect of scrubbing in a standard manner. The experiment shown in the accompanying table and chart will serve as an example to illustrate more fully application of the test.

The method also permits a much more accurate study of the bacterial flora of the skin than has been possible heretofore, lending itself admirably to investigation of the size and location of the bacterial flora as well as qualitative studies of the flora at various stages of degeneration, the mechanism of degeneration and reestablishment of the usual flora after degeneration.<sup>1</sup>

With generous help from colleagues and various groups of students, I have applied this new quantitative method to a reexamination of certain aspects of surgical bacteriology and surgical technic. The study has extended over a period of several years. Some of our results and conclusions are reported briefly herewith. A full description of the test and a more detailed account of the work on which the following conclusions are based will be published elsewhere.

### A SUMMARY OF RESULTS AND CONCLUSIONS

The bacterial flora of normal skin is found to be composed of "transients" and "residents."

Transients may be present in enormous numbers at times, but as a rule relatively few are present on grossly clean hands or on clean protected (unexposed) skin.

From the Department of Surgery, Chee-loo University, China, and the Department of Pathology and Bacteriology, Johns Hopkins University School of Medicine.

1. The word degeneration is used here in preference to disinfection to designate reduction in the total number of bacteria present, irrespective of whether the organisms are or are not pathogenic.

Transients, which are collected from extraneous sources, are comparatively easy to remove or kill. That is not true of the basic flora. Hence tests of germicidal power, which utilize test bacteria placed on skin and exposed subsequently to some disinfectant, may give thoroughly misleading results.

The size of the basic (or resident) flora at any given time is the net result of factors constantly acting, some to increase, others to lessen, the bacterial "population." Increase results largely from multiplication of resident organisms already present. Decrease is brought about by washing, friction of clothing and influences deleterious to bacterial life. Certain transients change their status and become residents, but this process seems to be a slow one and how it takes place is not clear. But the fact that it does happen makes it important to disinfect contaminated hands without undue delay.

The resident flora of my hands and arms, under conditions of ordinary life, tends to strike an equilibrium at about eight million micro-organisms.

This flora is located not in the skin nor to any extent in glands or hair follicles but on the skin.

The basic flora includes some pathogenic germs. If hands are in frequent contact with contaminated objects a dangerously large proportion of the resident bacteria may be pathogens. In such a case it is almost impossible to disinfect the hands. In this hitherto unsuspected manner a person may become a carrier of virulent organisms.

Ethyl alcohol has a very narrow range of effective germicidal concentrations. The optimum germicidal strength, both in vitro and on the skin, is 70 per cent by weight (not by volume as ordinarily prepared).<sup>2</sup> At precisely this concentration, alcohol is more effective than any other hand disinfectant now in general use. Each minute spent in this particular solution (at 25 C.) has a degerming effect equivalent to about six and one-

Bacteriologic effect of washing the hands and arms in 78.5 per cent (by weight) alcohol for one minute. The broken line *a'd'* represents the rate at which the basic flora of the author's hands and arms always are degermed by scrubbing in a standard manner. The solid line *ab* indicates the effect of scrubbing eight minutes, while *cd* shows the result of scrubbing seven minutes in the second series of basins. The initial deviation, *aa'*, from the broken line is due to contaminating (transient) bacteria purposely placed on the hands at the outset. So, of the initial number of 2,822,000 organisms, only 1,350,000 were "resident." This relatively small flora was due to the hands and arms having been well degermed two days previously and the usual flora not yet having been reestablished. The second deviation, *bc*, was due to use of the alcohol. It is clear that, by scrubbing 4.2 minutes, *bc'*, the same effect (as *bc*) could have been obtained. *cd* is equivalent to *c'd'*. Hence each minute spent in this particular solution of alcohol may be said to be equivalent to 4.2 minutes of scrubbing.

Results of an Experiment Done to Determine the Effect of Washing in 78.5 Per Cent (by Weight) Alcohol on the Bacterial Flora of Hands and Arms

Basin	Scrubbing Time, Minutes	Total Bacterial Count for Basin, Organisms	Cumulative Totals Washed Off, Organisms	Actual Totals or Size of Flora Left, Organisms
				2,822,370 (a)
1	1	1,497,440	2,272,370	1,324,930
2	1	166,320	774,930	1,158,610
3	1	197,960	608,610	960,650
4	1	132,770	410,650	827,880
5	1	66,300	277,880	761,580
6	1	74,000	211,580	687,580
7	1	74,680	137,580	612,720
8	1	62,720	62,720	550,000 (b)
At this point hands and arms dried in the air and then washed without friction in 78.5 per cent (by weight) alcohol for exactly sixty seconds. Scrubbing resumed immediately. Temperature of alcohol 25 C.				
				318,595 (c)
9	1	30,070	178,595	288,525
10	1	31,840	148,525	256,685
11	1	22,655	116,685	234,030
12	1	28,420	94,030	205,610
13	1	24,360	69,610	181,250
14	1	17,730	41,250	163,520
15	1	23,520	23,520	140,000 (d)

(a) Total number of bacteria on the hands and arms at the beginning of the experiment; (b) after eight minutes of scrubbing; (c) after application of the germicide; (d) after the second period of scrubbing; b and d are arrived at by mathematical projection of the curves produced.

Scrubbing with brush, soap and warm water, as practiced by me, reduces this basic flora at a constant rate. Irrespective of the initial size of the flora, the number of bacteria is reduced by approximately one half with each six minutes of scrubbing. The kind of soap used makes no difference. Variations in the temperature of the water do not influence the rate appreciably. The amount of vigor used in brushing is a very important factor, however. Sterile water has been found to possess no advantage over ordinary tap water in reducing this flora.

half minutes of scrubbing. This effect may be increased considerably by friction, i. e. by rubbing with gauze or a rough wash cloth. Even slight variations from that particular concentration of alcohol results in marked decrease of bactericidal power. Sixty per cent by weight (about 70 per cent by volume) is almost worthless.

Mercury bichloride solutions do not reduce the flora on the skin appreciably. Paradoxically, a sterile cutaneous surface may be produced. This phenomenon is due, we believe, to the formation of a transparent "film" on the skin under which the bacteria are imprisoned. There conditions are so suitable to life that multiplication takes place, the existing bacterial flora doubling every fifty minutes. The "film" may be broken up, either with an alkaline sulfide or by prolonged friction, whereupon the bacteria are released uninjured.

The same phenomenon is observed when potassium mercuric iodide (biniodide) or Harrington's solution is used. Neither of these is a true germicide when applied to the skin. When tested, these agents should always be followed by an alkaline sulfide.

Kelly's method of hand disinfection (with hot saturated solutions of potassium permanganate and oxalic acid) is very effective. The procedure requires from two and one-half to more than five minutes, depending

2. It is important to differentiate clearly in solutions of alcohol between per cent by volume and per cent by weight. Per cent by weight solutions are exact and invariable. Per cent by volume solutions, as ordinarily prepared, are inexact and undependable owing to three uncontrolled variables—temperature expansion, specific gravity and reaction concentration. Thus 70 per cent alcohol by weight (always the same) is the equivalent of 76.8 per cent by volume if the latter is prepared at 15 C. but is the equivalent of 80.5 per cent by volume if the volumetric measurement is made at 25 C. Accurate weight per cent solutions can be prepared from commercial (95 per cent) alcohol with the help of hydrometer, thermometer and appropriate tables. The following formula will give a solution approximately 70 per cent by weight: 95 per cent alcohol at 25 C. 815 cc., plus cold distilled water sufficient to make 1,000 cc.

on the temperature of the solutions. The total degerming effects are equivalent to between twenty and thirty minutes of scrubbing.

The lime and soda method is also very effective. When rubbing with the paste was continued for four minutes the reduction of flora was as great as could be accomplished by twenty minutes of scrubbing.

Saponated solution of cresol, though a relatively strong germicide against test organisms *in vitro* (a claim which we have verified), proved worthless as a disinfectant of the skin; 1:400 and 1:200 solutions, used without friction at 25 C., do not reduce the flora appreciably. In 1:100 solution, which causes some burning and anesthesia of skin, the flora is reduced about as rapidly (or as slowly) as scrubbing.

A search for a more nearly ideal hand disinfectant has resulted in the production of a new germicidal mixture which seems to possess certain advantages over any of the agents now in general use. It is powerfully germicidal, each minute spent in it (at 25 C., without friction) being equivalent to more than eleven minutes of scrubbing. It is simple and pleasant to use. It does not irritate or injure the skin. It is more stable than simple ethyl alcohol solutions. This germicide consists of ethyl alcohol 50 parts by weight, normal propyl alcohol 20 parts by weight and water 30 parts by weight. It may be prepared as follows: ethyl alcohol (95 per cent) 675 cc., pure n-propyl alcohol 250 cc., distilled water 250 cc., all measurements being made at 25 C.

By rational and conscientious use of the most effective means, the bacterial flora of the hands can be reduced to a relatively low figure but practically never to zero. The remaining organisms may, and on surgeons' hands often do, include pathogens. Hence the necessity for wearing gloves when operating.

Beneath rubber gloves, however, the bacteria remaining on the skin multiply rapidly, their number doubling every forty minutes if the hands are dry or every fifty minutes if the gloves have been put on wet. If gloves are worn long enough, the cutaneous flora may increase until it exceeds by far the ordinary flora. I found that on one occasion the bacterial count of my hands and arms had increased to more than 31,000,000. If pathogens are present they participate proportionately in this multiplication. No means has yet been found to prevent or delay this increase. These extraordinary bacterial "populations," we find, cannot be reduced any more rapidly than the ordinary. This phenomenon of rapid increase of cutaneous flora does not occur under cotton gloves or ordinary clothing.

The basic flora of protected skin per unit area is no smaller than that of the hands.

Ether, a representative of a group of the stronger germicides thought to disinfect skin chiefly by means of detergent properties, when subjected to our quantitative test proved utterly powerless to reduce the basic flora of clean skin.

Freshly prepared U. S. P. tincture of iodine (7 per cent), applied to grease-free skin and followed by an antidote, came nearer to full sterilization of the epidermis than any other germicide tested. U. S. P. "half-strength" tincture of iodine (3.5 per cent) proved far less effective, reducing the flora irregularly, but on the average by less than half. Two per cent iodine in 70 per cent (by weight) alcohol was much more effective, lowering the bacterial count to nearly 18 per cent of its original size. On drying, the germicidal action of iodine

practically ceases. The 2 per cent iodine in 70 per cent alcohol solution has certain important advantages: even spread, slow evaporation, nonirritation, and contributory bactericidal effect of the 70 per cent alcohol.

Mercurochrome, a prominent representative of a large group of the newer germicides, the organic compounds of mercury or silver, was tested. From bacteriostatic and bacteriocidal standpoints, mercurochrome was found to be similar in many respects to the inorganic salts of mercury. If no antidote is used, an exaggerated idea of its germicidal power is obtained. Aqueous solutions of mercurochrome on the skin may produce a nearly germ-free surface, but subsequent use of 10 per cent ammonium sulfide will show that the bacterial flora has been reduced little if any. Scott's alcohol-acetone-2 per cent solution of mercurochrome, applied liberally and allowed to dry slowly, reduced the bacteria of the skin to about one-third their original number. This whole group of germicides, the organic compounds of heavy metals, needs to be reinvestigated, appropriate antidotes being used.

After the skin has been degermed, reestablishment of the usual flora proceeds slowly (except under rubber gloves), apparently at a rate represented by a sigmoid curve. When the hands and arms have been thoroughly "disinfected," the number of bacteria being reduced, say, to 200,000, full reestablishment of the ordinary flora may be expected in about a week.

Parallel studies of our quantitative test on the one hand and the commonly used scraping and rubbing tests for cutaneous contamination on the other show that both of those time-honored methods become increasingly untrustworthy as the flora of the skin diminishes.

#### PRACTICAL RECOMMENDATIONS

The following principles and procedures are based on our experimental studies. Before recommending them, however, we subjected them critically to a prolonged test of clinical application, with highly satisfactory results.

*Preoperative Preparation of Hands.*—1. The hands are scrubbed with soap, a good brush and warm water for at least seven minutes. This will usually suffice to remove gross dirt, transient bacteria and fats, and incidentally about half the basic flora. The nails should be short and clean at the start.

2. The resident flora is much more effectively attacked by germicides than by scrubbing. We recommend ethyl alcohol, 70 per cent by weight, or the mixture of alcohols described. These solutions should be freshly and accurately prepared. Before entering the alcohol basin, the hands and arms should be dried thoroughly with a sterile towel, for to carry water into the alcohol will weaken the solution and markedly lessen its germicidal power. In the alcohol basin the skin should be rubbed firmly with sterile gauze or a washcloth.

The time spent in these solutions is of the utmost importance. We suggest that ethyl alcohol be used with friction for three minutes by the clock or the mixture of alcohols for two. This may be expected to reduce the original flora from 50 per cent (result of scrubbing) to something less than 2 per cent.

The occasional operator will increase the margin of safety by washing also in a 1:1,000 bichloride or 1:500 biniodide solution for one minute. The mercuric salt should follow, never precede, the alcohol, for the film formed by the mercurial is impervious to alcohol as well

as to bacteria. Bichloride, biniodide and Harrington's solutions are not recommended, however, for hands that must be disinfected frequently.

3. Gloves and gown are put on. An ungloved hand inevitably increases the risk of wound infection. In operating rooms where expense is not a major consideration, where only perfect (unpatched) gloves are used and where preparation of gloves are in highly competent hands, we have shown dry gloves to be preferable, and even safer. Elsewhere wet gloves will probably have a larger margin of safety. In lieu of gloves, the operator should wash his hands in bichloride or biniodide of mercury.

4. Between operations the hands should be washed in a germicidal solution in order to counteract the increase of cutaneous bacteria which has taken place beneath the gloves. A useful rule is one minute in alcohol for every hour that the gloves have been worn.

*Preparation of the Field of Operation.*—Preparation of the patient's skin the day before operation by wrapping the part in sterile towels is psychologically harmful and bacteriologically useless. Before coming to the operating room the patient should receive a bath, however, the site of operation being especially well washed with soap and water to remove dirt, most of the fats and any transient bacteria. If, as in the presence of a wound, this is not possible, a chemical detergent should be used.

Immediately before operation the site of incision should be washed with gauze and 70 per cent (by weight) alcohol or the suggested mixture of alcohols. It should be allowed to dry slowly, for in disinfection time is a factor that cannot be ignored.

This is to be followed by one of the stronger germicides. U. S. P. tincture of iodine (7 per cent) is extremely effective but in many cases too strong a solution to be tolerated or used safely. We recommend weaker solutions of iodine dissolved in 70 per cent (by weight) alcohol. After application, iodine solutions should be permitted to dry slowly. Washing a dried coat of iodine off the skin with alcohol increases rather than diminishes the total germicidal effect.

As an alternative to the iodine technic, the field of operation may be painted with Scott's alcohol-acetone-2 per cent solution of mercurochrome, or an irregular area such as that of the hand or foot may be soaked for a minute in 1:500 biniodide solution. In either case an aseptic surface will be produced. But the line of incision must first be specially prepared (disinfected), else the knife will necessarily pass through germ-laden skin beneath the "film." One way to do this is to rub the site of incision for two or three minutes firmly with gauze and 70 per cent (by weight) alcohol or our mixture of alcohols.

*Disinfection of Contaminated Hands.*—Ordinary hands, contaminated by contact with infectious patients or materials, are not difficult to disinfect. Saponated solution of cresol, however, is almost useless for the purpose, and solutions of bichloride or biniodide of mercury may be actually dangerous. We recommend the following as a simple dependable method for routine use:

1. The hands should be washed as soon as possible with soap and running water for at least thirty seconds. This may be expected to remove about nine tenths of the contaminating organisms. If there is pus, blood,

secretion from the wound, saliva, mucus or other infectious material on the hands, washing should be continued for a minute or more, perhaps with the use of a brush.

2. The hands should be well dried on an individual towel.

3. Every part of the hands should be wet with 70 per cent (by weight) alcohol. A few cubic centimeters dripped on the hands will suffice. The alcohol should not be wiped or shaken off but the skin should be allowed to dry by evaporation. It is the germicidal action that is required, and that takes time.

## PHOTOGRAPHY OF THE UTERINE CERVIX

CHARLES EDWIN GALLOWAY, M.D.

Assistant Professor of Obstetrics and Gynecology, Northwestern University Medical School and the Evanston Hospital

EVANSTON, ILL.

The present knowledge of medicine must be handed on to students, and teaching can be accomplished more advantageously with a combination of auditory and visual methods than by either method alone. Photographs are also of value to the practitioner as office records. The physician may wish to know what the exact appearance of the cervix, or any other lesion, was six months previously.

The patient also appreciates knowing why the cervix or other inaccessible part of the body needs repair or other treatment. She has no idea of the appearance of the cervix because she has never seen it and has never been aware of any sensation from it, since there are no sensory nerve endings in it. No other part of the body undergoes as much injury or is so neglected after being injured. The cervix is also the sharp junction of two distinctly different types of epithelium, which means that it is constantly subject to change due to the erosion and healing processes going on in such an area. Other parts of the body may lend themselves just as readily as the cervix to photographic records. Portrayal of operative procedures and photographs of pathologic tissue in situ are both valuable and should be preserved not only for records but for use in teaching.

In the field of gynecology and obstetrics, teaching material is somewhat more difficult to find than in other branches of medicine; therefore, every effort possible must be made to record by accurate drawings and photographs examples of pathologic lesions and normal tissue.

Not only must this material be recorded, but it must be done in such a way that it is easily available for teaching purposes. The records must be where they can be readily shown and they must be shown repeatedly.

Students spend long hours in clinics attempting to see examples of lesions about which they have read, but most find by the time their course is over that there are many important lesions which they have not had an opportunity to see. By making accurate colored photographs over a period of years of the many differ-

Read before the Section on Obstetrics and Gynecology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

ent cases, one can supplement the reading course by actual photographs in color.

With these points in mind, I have for the past several years been attempting to devise a means whereby good photographs could be made with the least possible expenditure of time and with the least discomfort to the patient. The various devices assembled here are by no means perfect, but this paper is published with the hope that others interested will contribute valuable suggestions.

Many difficulties were encountered in an attempt to photograph as small an object as the cervix at close range. The usual tripod was found to be too cumbersome; a single shaft on a heavy round metal base has proved much easier to handle. It can be placed close

Another difficulty was the distance from object to camera, and this was overcome most readily by using a Speed-o-Copy attachment with three extension tubes and a 90 mm. f/4.5 telephoto lens. With the use of this attachment, extension tubes and telephoto lens, the image on the colored film is approximately life size and the end of the lens is kept 18 cm. from the cervix. This distance allows the lens to escape touching the speculum. The Speed-o-Copy attachment has a ground glass for focusing, and over this is a detachable magnifying lens which makes possible a very accurate focus. When the cervix is in sharp focus the ground glass and lens swing up, the camera lifts up into the position formerly held by the ground glass, and it is locked there while the exposure is made (figs. 1 and 2).

A third difficulty was proper illumination of the cervix. Various speculums with lights built inside were tried, but none were bright enough and most of them caused discomfort. Two "Good-Lites" are now used, one on either side of the lens, and they are fastened to the base of the Speed-o-Copy attachment by small universal joints. These lights are commonly used by otolaryngologists on a headband. The rheostats for the lights are attached to the standard and help to lend weight.

Fig. 1.—Camera in position for focusing. A, Leica camera; B, Speed-o-Copy (D. Paul Shull, manufacturer, Los Angeles) with three extension tubes; C, 90 mm. f/4.5 lens; D, two "Good-Lites"; E, microscope stage attached above to base of Speed-o-Copy and below to F, Leica universal ball joint; G, rheostat cords; H, expansion screw allowing inner rod to be raised and lowered.

to the examining table and moved easily forward or backward to the approximate focal distance. This rod is so constructed as to allow the camera to be either raised or lowered. A small candid camera lends itself to quick work, but any other camera may be used. Up to the present time, the best colored film is available only in 35 mm. size, and since it gives a very accurate colored picture the small candid camera seemed best to start with. The camera is not permanently attached to the assembly of the various devices but may be used as a candid camera merely by unscrewing it from the Speed-o-Copy attachment and replacing the usual lens. In other words, the use of the camera is not restricted to the office or clinic but is available for other purposes.

Fig. 2.—Camera in position for making picture.

Fig. 3.—Bivalve black nickel vaginal speculum and piece of thin rubber Penrose tube.

Another problem was to obtain an accurate focus. In order to get this quickly the whole outfit was attached by a rigid tubular post to a microscope stage.

By turning the screw of this stage, one moves the camera and all its attachments forward or backward in the same plane. The entire assembly is attached to the standard by a large ball universal joint which allows it to be pointed in any direction the vaginal canal may assume. Once the mechanism is placed at the proper height and directed properly, the microscope stage permits a quick accurate focus.

Getting proper exposure of the cervix and an aperture through which a photograph could be taken was another perplexity. The comfort of the patient is of great importance and must be considered, for she must wait until the camera is adjusted properly. A large-sized bivalve speculum was found to be the most comfortable and still permit an aperture large enough; made of black nickel, it gives very little reflection. In order to hold the lateral vaginal walls back, a piece of large-sized Penrose rubber drain may be pulled on to the speculum before it is inserted. As the blades are spread apart, the tension caused by stretching the rubber keeps the vaginal walls perpendicular (figs. 3, 4 and 5).

Kodachrome film is used and the films are mounted as lantern slides. The slides,  $3\frac{1}{4}$  by  $4\frac{1}{4}$  inches (8.2 by 10.8 cm.), are made for regular stereopticons because much more light is available in them; however, the small slide, 1 by  $1\frac{1}{2}$  inches (2.5 by 3.8 cm.), may be used. Kodachrome film has no grain in it and with a 1,000 watt lamp and a  $6\frac{1}{2}$  inch (16.5 cm.) lens on a projector, a small 35 mm. picture can be made approximately 10 feet square at 40 feet with no loss of fine detail.

Black and white film can also be used, and from these negatives enlargements are made. In order to increase the depth of focus, the lens is closed to f/9 or smaller, and it has been found that an exposure of four

Fig. 4.—Rubber tubing drawn over blades of speculum and ready for insertion.

fifths of a second at f/9 has been satisfactory in most of our work. One light may be a little less bright, thus overcoming some of the difficulty in photographing a spherical object. This, however, is not necessary when Kodachrome film is used, since the color itself gives the impression of depth in the photograph. Photographs can be made in from five to ten minutes with the use of this mechanism and, as every one knows, the saving of time is desirable during a busy office or clinic period.

This assembly has not been patented and will not be; however, the various parts of which it is composed are patented articles. The mechanism is being assembled by the General Scientific Instrument Company of Chicago, and I do not and will not receive any remuneration from it. It is only hoped that others will be stimulated to make good photographs, not of the cervix alone but of lesions in other organs, and will report their work at some future date.

636 Church Street.

#### ABSTRACT OF DISCUSSION

DR. J. M. BRUNER, Des Moines, Iowa: I should like to express my appreciation of Dr. Galloway's paper. Heretofore lesions of the cervix have been illustrated by drawings, which

Fig. 5.—As the speculum blades are separated the tension caused by stretching the rubber keeps the lateral vaginal walls perpendicular.

were often inaccurate. It is surprising that no good photographs of the cervix are to be found in textbooks. Years ago my attention was called to this fact by an article by Mr. Ralph P. Creer of Chicago (*Photography of the Cervix Uteri, Journal of the Biological Photographic Association*, December 1935). At the time I was conducting one of the gynecology clinics of the Broadlawns County Hospital at Des Moines, Iowa. Many interesting lesions of the cervix were being seen, and it seemed desirable to make a photographic record of these lesions before and after treatment. For this purpose I designed a special tubular speculum which provides unexcelled exposure of the cervix for photography. The lights are placed within the speculum on one side only, in order to produce the maximum degree of modeling in the cervix. The camera used is a Leica with sliding ground-glass attachment. The technique for this work was published in an article by Dr. L. E. Rosebrook and myself in the *Journal of the Biological Photographic Association*, September 1936, and in the *American Journal of Obstetrics and Gynecology*, December 1937. Color photographs of the cervix make beautiful lantern slides. Such photographs, however, cannot be reproduced for publication. For this purpose black and white negatives are essential. Good black and white negatives are much more difficult to obtain because they lack the third dimensional properties of color film. They do, however, make excellent illustrations for textbooks and scientific articles.

**No Life Without Proteins.**—Proteins represent the stream of life. They make up the vital part of that essential jelly material of the living cell—the protoplasm. The beginning of life on this and perhaps a few other fortunate planets must have been associated with the formation of proteins. This word means "to take first place," for there is no life without proteins. The name was the lucky choice of Mulder, one of the first investigators.—Furnas, C. C., and Furnas, S. M.: *Man, Bread and Destiny*, New York, Reynal & Hitchcock, 1937.

REOPENING LIGATED TUBES BY  
UTERINE INSUFFLATION WITH  
CARBON DIOXIDEI. C. RUBIN, M.D.  
Gynecologist, Mount Sinai Hospital  
NEW YORK

Surgical sterilization by tubal ligation has a disquieting effect on some patients, leaving them unreconciled to the artificially induced sterility. Certain circumstances besides remorse and psychic depression occasionally arise after surgical sterilization which make the retrieval of the forfeited fertility eminently desirable. Such is the loss of an only child or more rarely the loss of two or three children or marriage to a second husband with whom children are keenly desired. The loss of fertility is particularly felt by women whose health is unexpectedly improved or wholly restored.

To remove the obstacle to conception, another laparotomy must be considered. But since this involves the risk of a surgical operation, postoperative convalescence and possibly also an economic burden, it is not particularly agreeable to the patient nor is it readily assented to by the husband.

For such women any method that might accomplish the reopening of the tubes without necessarily resorting to a laparotomy would appear to meet a real need. In uterotubal insufflation a nonoperative method has been found which offers this possibility. Its application for this purpose is supported by a number of successful therapeutic results following uterotubal insufflation in cases of involuntary sterility due to strictures of the fallopian tubes and peritubal adhesions. In these cases pregnancy has occurred within one or several months after treatment. The pressure to which the carbon dioxide is raised in these strictured tubes often reaches

Chart 1.—Tubal insufflation Oct. 1, 1931. Initial rise of pressure to 170 mm. of mercury; sharp drop at point where the obstruction was relieved to 60 mm. and 25 mm., after which strong tubal contraction waves were recorded typical of normally patent fallopian tubes.

200 mm. of mercury before patency is established. By widening the opening in the tubal lumen, the impediment to conception is removed.

An accidental observation made in 1931 on a patient who had been sterilized by tubal ligation gave the clue to the possible therapeutic use of carbon dioxide insufflation after ligation of the tubes. D. S. had an only child who had been delivered by cesarean section, at which time the fallopian tubes were tied and cut and

the severed lumens were peritonealized. Contemplating remarriage, she wanted to know whether she could possibly conceive again. During tubal insufflation the pressure rose to 170 mm. of mercury and suddenly dropped to 60 mm., after which rhythmic contractions and relaxations were recorded on the kymograph drum (chart 1). There were typical shoulder pains, and a subphrenic pneumoperitoneum was demonstrable fluoroscopically. She became pregnant two years after this examination. Several years later a uterine insufflation showed the tubes to be open within normal limits and functioning (chart 2).

I did not have occasion to reopen ligated tubes by this method until 1937, when this question arose in connection with a study of the Head zones and distri-

Chart 2.—Tubal insufflation in same patient Oct. 11, 1937, showing tubal patency at normal pressure levels.

bution of pain coincident to tubal distention which was produced by uterine insufflation with carbon dioxide.<sup>1</sup> The study was made in young women who had recently been sterilized by tubal ligation. The ligatures had been intentionally placed at different portions of the fallopian tubes. It was found that when the pressure exceeded 120 mm. of mercury there was a sudden sharp drop, indicating that the tube or tubes yielded at the ligated points. The carbon dioxide passed into the peritoneal cavity and the tubes exhibited rhythmic contractions. Since the sterilization was indicated on medical grounds, these patients were duly instructed in contraception.

Based on five similar experiences, it seems justifiable to say that one or several of the women whose tubes were reopened could become pregnant again if they chose to. This possibility obviously puts a different psychologic aspect on tubal ligation in the case of women who hope for a return of reproductive function. The assurance of retrievability enabled three patients during the past year to go through the operation with an untroubled mind.

As to the manner in which insufflation opens up ligated tubes, it has been noted that whether the tubes are previously crushed, as in the Madlener operation, or not crushed, as in the Pomeroy method, the operations which are preferred by most surgeons, the pathologic change induced is localized at the point of ligation. Observations on the local condition following the operation are fairly uniform. A small fibrous band connects the severed end of the tubal loop, or fine adhesions bind them to adjacent viscera.<sup>2</sup> The stricture, though complete, is limited to a very thin segment of the endosalpinx and tubal serosa in contrast to pathologic strictures, which as a rule occupy more extensive portions of the lumen of the tube.

As fallopian tubes that have been ligated were normal previous to the sterilizing operation, they remain normal except at the point of ligation. This renders the surgical stricture vulnerable to intratubal pressure.

1. Rubin, I. C.: Study of Pelvic Pain and Head Zones Reproduced by Artificial Distention of Ligated Fallopian Tubes, *J. Mount Sinai Hosp.*, to be published.

2. Bishop, Eliot: Operative Methods of Sterilization in the Female, *Am. J. Obst. & Gynec.* 34: 505 (Sept.) 1937.

When it becomes desirable to reestablish tubal patency after the Madlener or Pomeroy operation, the same technic of uterotubal insufflation can be adopted as in testing for tubal patency in cases of involuntary sterility. When I originally suggested this method to test the security of tubal ligation, I did not realize that higher pressures than those required for normal patency might overcome the artificially induced obstruction. Later experience has shown that this is possible. In this connection it is not altogether strange that pregnancy should follow the opening of otherwise normal tubes which have been ligated and severed at different points for purposes of sterilization, since pregnancy has been known to occur in cases in which diseased tubes were resected at practically any point of their entire length, including the uterine insertion.

Patency was reestablished in five cases following tubal ligation by pressures below 160 mm. of mercury. The operation of ligation had been performed by different gynecologists. Apparently the more recent the ligation the less pressure is required to open up the tubes. Unless the interstitial portion of the tube has been resected, the artificially induced obstruction should yield to insufflation at a pressure of 200 mm. of mercury or less. In experienced hands the pressure level may be increased to 250 mm. of mercury. The latter, however, is recommended only as a therapeutic measure for the specific purpose of effecting a reopening of ligated tubes. If the insufflation fails on the first trial to open the tubes, it can be conveniently repeated at suitable intervals. Should pregnancy not soon take place though tubal patency has been restored, the patient has the reassurance that the mechanical closure is no longer responsible for the sterility.

The question naturally arises whether fluid mediums may not be used instead of carbon dioxide to reopen ligated tubes. If iodized poppyseed oil or other iodized oils are considered there are several disadvantages: 1. Retention of oil at or near the tight opening may induce foreign body reaction and organic obliteration.<sup>3</sup> 2. The pressure control is not as accurate as when carbon dioxide is used. 3. The injection of iodized oils cannot be repeated as conveniently and safely as insufflation with carbon dioxide. The latter has the great advantage of being used under a constant rate of flow, regulated by a reduction valve, the gas being promptly resorbed and leaving no residue.

If one prefers to employ fluids it is advisable to use skiodan, hippuran or any of the quickly resorbable crystalloids of iodine, which can be injected with the aid of the kymographic insufflation apparatus. I have not used these radiopaque mediums for this purpose because the data with regard to the points of ligation, the only point to be adduced by opaque mediums, were already available. If such data should not be at hand, one could locate the obstructions by the insufflation method.<sup>4</sup>

As to the technic, it is only necessary to mention that the flow of carbon dioxide is regulated at the rate of 1 cc. per second or slower, the pressure rise and pain reaction being observed if any are present. About 100 cc. of gas is adequate and the procedure requires from two to three minutes at the first trial.

911 Park Avenue.

## TETRALOGY OF FALLOT

REPORT OF A CASE IN A MAN WHO LIVED  
TO HIS FORTY-FIRST YEAR

ITALO F. VOLINI, M.D.

AND

NATHAN FLAXMAN, M.D.

CHICAGO

A major congenital anomaly of the heart associated with the development of the bulbus cordis<sup>1</sup> is the unusual and rare condition first noted by Peacock<sup>2</sup> and later fully described by Fallot.<sup>3</sup> The tetralogy of Fallot consists of the combination of an interventricular septal defect, pulmonary stenosis and insufficiency, dextroposition of the aorta and hypertrophy of the right ventricle. Abbott<sup>4</sup> ascribed this combination of lesions, largely on the basis of studies by Keith, to an arrest of development before the eighth week of embryonic life. She<sup>5</sup> cited seventy-three cases of the tetralogy in her comprehensive summary of the literature in 1928. The oldest patient in her series was 36 years of age and the average age in the series was 11 years.

The outstanding case of this type in the literature is the report by White and Sprague<sup>6</sup> of a noted musician who lived to his sixtieth year, surpassing in age all patients previously reported by more than twenty-three years. Leadingham<sup>7</sup> reported the case of a white girl aged 15 years who had been short of breath and cyanotic all her life; the cause of death was a subacute bacterial endocarditis of the pulmonary valve which had caused occlusion of the narrow pulmonary orifice. Blackford<sup>8</sup> related a clinical case in a Negro youth aged 20 who had always been short of breath, had clubbed fingers, and had the usual polycythemia. White and Boyes<sup>9</sup> cited the case in a white woman aged 21 with the tetralogy but whose death was due to a subacute bacterial endocarditis of the tricuspid valve and the pulmonary artery. Segall's<sup>10</sup> case of a white man aged 23 had been discussed by Abbott<sup>5</sup> in her review. Two other cases were reported in infants;<sup>11</sup> in one there was also a redundant left ductus arteriosus and in the other an anomalous band in the right auricle.

A much rarer congenital anomaly of the heart similar to this tetralogy is the Eisenmenger<sup>12</sup> type, described

From the Departments of Medicine, Cook County Hospital and Loyola University School of Medicine.

by him in 1897, which presents no pulmonary stenosis but a thick, wide pulmonary conus, so that a pulmonary insufficiency without obstruction is present. Baumgartner and Abbott<sup>13</sup> reported a case of this type in a white man aged 20 presenting impaired conduction and paralysis of the recurrent laryngeal nerve from pressure of the hypertrophied pulmonary conus; the patient died of a cerebral abscess. Rosedale<sup>14</sup> reported a third case of the Eisenmenger type in a white boy aged 10 years. Talley and Fowler<sup>15</sup> reported the fourth case of this kind in a white woman aged 31 who had had a normal physical and mental development, had passed through two pregnancies and had been able to take care of her house until a month before her death.

The case of the tetralogy of Fallot that we report is the first in which a clinical diagnosis was established (I. F. V.) and confirmed at postmortem examination

Fig. 1.—Electrocardiographic tracing in tetralogy of Fallot. Note prolonged PR conduction, right axis deviation, gross distortion of ventricular complexes and prolonged ST interval.

in the Cook County Hospital. The rarity of congenital heart disease at such a large institution may well be emphasized, as only ninety-nine cases (1 per cent) have been noted in 9,500 autopsy protocols in the period from 1929 to 1938. This incidence of congenital heart disease may be compared with and is as common at the Massachusetts General Hospital,<sup>16</sup> where sixty-seven cases (0.9 per cent) were noted in 7,500 postmortem examinations, and at the Johns Hopkins Hospital,<sup>17</sup> where 170 cases (1.29 per cent) were noted in 13,115 autopsies. Our case is also of unusual interest because the patient lived to the age of 41 years, five years longer than in any case reported previously with the exception of that of the noted musician,<sup>6</sup> and the cause of death was not in any way connected with the multiple cardiac abnormalities.

#### REPORT OF CASE

A man aged 41, a laborer, fairly well developed, was admitted to the medical service of the Cook County Hospital June 4, 1936, complaining of shortness of breath of thirty-five years' duration and swelling of the legs on and off during the past five years. He had had "heart trouble" as long as he could remember. Except for the shortness of breath he had been fairly well until 1931, when his legs became swollen. The swelling persisted a few weeks and then disappeared, only to return again. He had been attending the cardiac clinic of a medical

dispensary very irregularly for the previous five years. The day before admission to the hospital he had a "fainting spell" and fell, injuring the right circumorbital region.

Marked cyanosis and clubbed fingers were evident. A diffuse apex impulse was visible in the sixth left intercostal space at the midaxillary line. There was a palpable systolic thrill over the entire precordial area. The right border of the heart was 6 cm. to the right of the midsternal line, and the left border was in the midaxillary line. The systolic blood pressure was 168, the diastolic 100, the pulse rate 56. There was a long, very loud systolic murmur audible over the entire precordial area and over the cardiac area well to the right of the sternum. This long murmur was propagated upward into the vessels of the neck. There was a long diastolic murmur with the punctum maximum at the third left intercostal space at the margin of the sternum. The systolic murmur over the aortic and pulmonic areas was much louder than the diastolic murmur. The liver edge was palpable below the right costal margin. There was brown pigmentation, thickening with lichenification, and scaling of the skin on the lower half of the legs.

Fig. 2.—Heart shadow occupies most of the lower part of the chest. The wide vessel shadow at the base is due to the widely dilated first portion of the aorta.

32636

An electrocardiogram taken June 8 revealed an unusual picture (fig. 1). The rate was 60 and regular. Right axis deviation was noted. The P waves were prominent in all leads but diphasic in lead 3. The PR interval was prolonged to 0.28 second. The QRS complex was 0.08 second and grossly notched. The ST interval, while isoelectric, was prolonged, measuring 0.28 second. The T waves were inverted

Fig. 4.—Anterior view with open right ventricle. Aorta and pulmonary artery arise from the right ventricle. The interseptum defect is indicated by the tails of the arrow, with the arrowhead in the rightsided aorta. Vertical glass rod extends from the right ventricle into the stenosed pulmonary artery.

in leads 2 and 3. This abnormal type of electrocardiogram was interpreted as being related, probably, to the anatomic variations in the bundle of His and its branches, induced by the basal interventricular septal defect. Impulse transmission must have necessarily taken an abnormal course over the conduction system because of the distortion of the conducting mechanism. The prolonged PR interval, however, may have been the result of the uremic syndrome.

Fluoroscopy of the chest revealed considerable enlargement of the right border of the heart with marked enlargement also to the left and upward. The pulmonary conus was not visualized. Barium sulfate by mouth showed a diminished retrocardiac space but no compression of the esophagus. A 2 meter chest plate revealed enormous cardiac enlargement (fig. 2).

Chemical analysis of the blood taken on the same day revealed a urea nitrogen content of 130 and a creatinine content of 11 mg. per hundred cubic centimeters. The patient's condition changed at 2 p. m. June 9, when generalized clonic convulsions occurred. He became drowsy, sank into a deep stupor with Cheyne-Stokes respiration and died June 11, with a terminal picture of uremia. Chemical analysis of the blood on the last day of life showed a urea nitrogen content of 133 and a creatinine content of 10.75 mg. per hundred cubic centimeters.

At postmortem examination (Dr. R. H. Jaffé) the pericardial sac extended from the right costochondral junction to the left midaxillary line and compressed the left lower lobe of the lung. The heart weighed 750 Gm. The left ventricle measured 20 mm. and the right ventricle 18 mm. The myocardium was firm and a light purplish brown. The apex was formed by the right ventricle. The epicardium was smooth and shiny. The

left auricle was slightly dilated and the thickness of the wall measured 1 mm. The foramen ovale measured 6 mm. in the longitudinal and 3 mm. in the greatest transverse diameter. It was covered by a fold which overlapped the opening completely. The mitral valve was of normal configuration.

In the uppermost portion of the interventricular septum there was a crescent-shaped defect 30 mm. in transverse and 12 mm. in vertical diameter. This defect, which was located opposite the anterior cusp of the mitral valve, led into the pulmonary conus and formed the only outlet of the left ventricle.

The aorta originated from the right ventricle and measured 120 mm. in circumference. The aortic valve had four leaflets; about the middle leaflet the left coronary artery originated, while about the right leaflet the right artery originated.

The pulmonary artery was located to the left and posteriorly to the left leaflet of the aortic valve. The pulmonary artery extended into the right ventricle for a distance of 3 cm. as a constricted tube lying on the right ventricular surface of the interventricular septum close to the anterior origin of the latter. The pulmonary ostium was thus about 3 cm. below the level of the aortic valve leaflet attachments and the opening was constricted to a circumference of 3 cm., as was the intraventricular portion, but then it widened to 53 mm. in circumference. The pulmonary artery was thin walled, with a smooth intimal lining. The pulmonary valve had two leaflets which were fused together to form a circular fold, which was evidently incompetent. The right auricle was markedly dilated, about 8.5 cm. in transverse diameter. The tricuspid valve was of normal configuration.

The lungs were moderately distended and subcrepitant. The main pulmonary artery was of normal configuration. On section it was a purple-gray and moderately moist. There were scattered fatty plaques in the pulmonary artery. On microscopic section no difference was noted in caliber between the branches of the pulmonary artery and the bronchial arteries.

Fig. 5.—Anterior view showing right ventricle and right aorta. Note the thickness of the right ventricular wall. The greatly dilated first portion of the aorta with the great vessel branches derived from this portion.

The kidneys weighed 225 Gm. and were moderately firm, and the capsule stripped with ease. The surface was a light purple-gray and uniformly granular. The granules were of pinhead size. The cortex measured 7 mm. and was purplish gray, but the markings were distinct. Microscopic examination of the

kidney sections revealed that the majority of glomeruli were completely or partially hyalinized. The remaining glomeruli were large and very cellular with the capsular space often obliterated. Many of the tubuli contorti were atrophic with a corresponding increase in the interstitial tissue. The granules were composed of hypertrophic tubules, the lumen of which was wide and the lining of which was cuboidal and finely granular. The larger arteries showed hypertrophy of the media, while the wall of the afferent and intralobular arterioles was slightly thickened. Sudan III stain revealed much fatty material, chiefly in the stroma in the form of nests of large cells filled with fat droplets. There was also some fat in the epithelium of some of the convoluted tubules and in the hyalinized glomeruli.

The complete anatomic diagnosis was chronic glomerulonephritis, detorsion defect of the large arteries of the heart with the origin of the aorta and pulmonary artery from the right ventricle, stenosis of the pulmonary ostium, defect of the interventricular septum, patent foramen ovale, hypertrophy of

men ovale was slitlike and covered by a fold, so that in all probability it was functionally closed. The development of the conus arteriosus was clearly demonstrated by the side to side position of the aorta and pulmonary artery, with complete coats, however, separating these vessels. The first portion of the aorta was evenly dilated and the major blood vessels came directly from this enlarged sac. The arch was poorly developed and the aorta, after leaving this saclike first portion, was comparatively small and narrow, measuring 40 mm. in diameter in the second portion and 36 mm. in diameter in the third portion.

#### SUMMARY

In an unusual case of the tetralogy of Fallot in a laborer who lived to his forty-first year, the second longest history in the literature, the clinical diagnosis was established according to Fallot's original descriptions. It is the only case of its kind which has come to autopsy in the records of the Cook County Hospital, where congenital heart disease of all types represents only 1 per cent of the postmortem material. The senior author, who has had a long association with this institution, has seen only one other adult<sup>18</sup> with congenital heart disease who lived longer than the patient in the present instance. The cause of death in our case was not due to any cardiac disturbance or dysfunction but to the uremic syndrome on the basis of chronic glomerulonephritis.

30 North Michigan Avenue—3507 Lawrence Avenue.

Fig. 6.—Posterior view of the heart with the right auricle and ventricle open. Glass rod through the slitlike interauricular septum defect.

both ventricles of the heart, especially the right, marked dilatation of the right auricle of the heart, slight atheroma of the aorta and the coronary arteries, passive congestion and edema of the lungs and compression atelectasis of the left lower lobe of the lung, marked hydropericardium and slight ascites and bilateral hydrothorax, slight edema of the brain, nodose goiter and prostatolithiasis.

#### COMMENT

The slight degree of disability which this patient demonstrated during life can probably be explained by several points: First, the interventricular septal defect was so located that the direction of the blood current from the left ventricular contraction was apparently directed into the aortic opening. Second, the mouth of the pulmonary artery was in the right ventricle, as this artery was intraventricular for about 3 cm. As this pulmonary ostium was just below and anterior to the interventricular septal defect, right ventricular contraction forced blood into the stenosed pulmonary artery opening rather than through the septal defect. The patent fora-

### Clinical Notes, Suggestions and New Instruments

#### BENIGN GRANULOMA OF THE NOSE (SO-CALLED SARCOID)

FRANK B. KISTNER, M.D., AND THOMAS D. ROBERTSON, M.D.  
PORTLAND, ORE.

Sarcoid cannot be considered a rare disease. It is, however, of considerable interest in that marked variations in clinical manifestations may occur, and it offers considerable difficulty in diagnosis in differentiating tuberculosis, syphilis and other types of proliferative granulomas.

There are several outstanding facts in the manifestations of sarcoid. The sites of particular involvement are the skin and the lymph nodes, more particularly the superficial lymph nodes; but the mediastinal lymph nodes may show massive involvement. The bones involved are most frequently those of the extremities, especially the smaller bones, where frequently destructive lesions are present. The long bones also may be involved. In a review of the literature almost every part of the body has been mentioned as being involved in this process, and while we have found reference made to involvement of the nasal bones<sup>1</sup> we have not encountered a report of involvement of the nasal mucosa.

The lesion histologically<sup>2</sup> is a granuloma composed of collections of epithelioid cells which occasionally surround giant cells of the foreign body type. There is rarely any necrosis. Tubercle bacilli are not found. The cutaneous test is almost uniformly negative.

Clinically the course is of a benign prolonged character and some lesions may progress while others are retrogressing.

2. Nickerson, D. A.: Boeck's Sarcoid: Report of Six Cases in Which Autopsies Were Made, Arch. Path. **24**: 19-29 (July) 1937.

There may be any combination of involvement, and the various syndromes described are purely clinical differentiations.<sup>3</sup>

From the standpoint of etiology, no single organism has been found to be present. A preponderance of evidence favors tuberculosis. Etiologic factors have been given also as leishmaniasis and leprosy; these seem unlikely. The finding of the

#### REPORT OF CASE

A widow aged 50 presented herself for the first time in December 1930 complaining of nasal obstruction of several years' duration. In January 1931 we did a submucous resection of the septum and removed the cystic middle turbinate. At the time of the original examination she said that she felt there was a lump coming on the left side of her nose but was not sure, since the nose had always been a little broad and asymmetrical. Nasal breathing was satisfactory after the submucous resection. She returned in May 1932, sixteen months after the operation on the septum. At this time she showed definite infection of both antrums. She again remarked that she felt that her nose was enlarging but could not be sure that there was any material change. The x-ray laboratory reported an increased density in both antrums, also that the nasal bones showed an unusual density, especially along the inferior margins. The Wassermann reaction was negative on this occasion and had been negative on the previous examination. The infection of the antrums did not improve under conservative treatment, and a bilateral Caldwell-Luc operation was done from which recovery was rapid and uneventful. The

Fig. 3.—Section showing the tubercle-like lesion among the osseous trabeculae of the nasal bone. The spaces between the trabeculae are widened by this fibroblastic and granulomatous tissue. There is a slight increase in the number of osteoblasts along the trabeculae of the bone.

drainage ceased and the function of the nose was satisfactory, but the aching across the upper part of the face continued. During the next two months we were sure that the nose was enlarging across the bridge, and material for biopsy was taken from the bone at the junction of the nasal bones and the ascending process of the superior maxilla, from the subcutaneous tissue and from the mucosa of the nose.

A summary of the pathologic report by Dr. Robertson was as follows: On cross examination the bony tissue appeared rather spongy and the mucosa was somewhat firmer than normal. It was pale. On microscopic examination sections of both the mucosa and the bone showed the presence of many discrete tubercle-like lesions scattered throughout. These consisted of clusters of epithelioid cells radiating out from the center, and in the center of some there was a giant cell. These giant cells occurred singly and showed a peripheral arrangement of the nuclei in the shape of a horseshoe. Some of the tubercles on close examination were seen to contain capillary blood vessels in which there were erythrocytes. No polymorphonuclear neutrophils were present. There were lymphocytes in the surrounding tissue. It seems that the tubercle-like lesions in places were juxtaposed to blood vessels, and the blood vessels seemed somewhat narrowed. There was a suggestion

of central necrosis in some of these tubercles, but this was not definite and at no place was there anything that had the appearance of true caseation necrosis. In the bony tissue these tubercles occurred in the fibrous tissue among the bone trabeculae; there was evidence of active proliferation of the bone manifested by an increased number of osteoblasts along the

Fig. 4.—At the center is seen a thick-walled blood vessel with marked perivascular round cell infiltration and in the nearby vicinity there are several of the tubercle-like lesions. This was thought possibly to indicate syphilis.

trabeculae. Bacterial stains failed to reveal any bacteria of any type. Spirochete stains were not made.

On the basis of a distinct granulomatous process, which was principally proliferative and appeared to be somewhat perivascular without caseation necrosis, it was thought that this might possibly be syphilis in spite of the fact that the Wassermann reaction was consistently negative. It was on this basis that a therapeutic trial of antisyphilitic treatment was given.

Sections of the mucous membrane of the antrum did not show any evidence of the granulomatous process. The pathologic diagnosis was chronic sinusitis.

On the basis of the pathologic report the patient was put on antisyphilitic treatment consisting of intermittent courses of neoarsphenamine and thiobismol from September 1932 until March 1935. The only positive improvement during this time was relief from the aching pain in the face. The enlargement of the nose was insidiously progressive.

During the spring of 1936 there appeared a discoloration of the skin of the nose, and the opinion of a dermatologist was sought. Following is the report of Dr. Lyle B. Kingery: "Dermatologic examination reveals a purplish, plaque-like infiltrative process involving the skin of practically the entire nose. The process presents a firm consistency, is painless and devoid of acute inflammatory symptoms. It is fairly well demarcated and macroscopically presents no epidermal changes. In addition, both inspection and palpation impressed me with the fact that there is a productive change involving the underlying structures, particularly at the juncture of the nasal bones with the superior maxilla. Pressure reveals this to be painless, hard and fairly regular.

"The presence of the purplish infiltration, the absence of general health impairment, the slow progress over an extended period of time and the location of the process all point to a diagnosis of sarcoid. While this is not common, there is apparently sufficient evidence of occasional bony involvement to make this a part of the picture. Finally, in talking with Dr. Robertson, I was pleased to have him state that this diagnosis was acceptable to him in a reconsideration of the results of his biopsy."

At Dr. Kingery's suggestion the patient was treated with x-rays and given solution of potassium arsenite and weekly injections of bismuth salicylate. These were continued with intermissions until June 1937, when all treatment was stopped. There had been a decided improvement, and we hoped the growth had been arrested. When she returned for examination in September it was discouragingly evident that the process had become active again and the treatment was resumed. To date there has been no improvement, but for the last three months the process has remained stationary.

#### SUMMARY

We have just reported a case of sarcoid or, better termed, benign granuloma of unknown etiology, involving the nasal mucosa, nasal bones and overlying skin. The considerable difficulty in arriving at a final diagnosis was encountered because of the unusual involvement of the nasal bones and nasal mucosa. With the involvement of the overlying skin Dr. Kingery uncovered the true nature of the disease process and a review of the sections confirms his interpretation.

#### GANGLIONEUROMA OF THE OVARY

HARRY C. SCHMEISSER, M.D., AND W. A. D. ANDERSON, M.D.  
MEMPHIS, TENN.

Tumors composed of such highly specialized tissue as adult ganglion cells and their processes are comparatively rare. McFarland,<sup>1</sup> who reported a case in 1931, was able to find

Fig. 1.—Ganglioneuroma of the ovary. Posterior view of the lobulated, soft, epithelial covered tumor. The parenchyma is yellow-pink, juicy, translucent, very vascular, extremely soft and easily picked away. The tube is shown above.

reference in the literature to ninety-three similar tumors. The literature was likewise reviewed in 1932 by Bigler and Hoyne,<sup>2</sup> who added two cases of their own.

From the Department of Pathology, University of Tennessee Pathological Institute.

We are indebted for the illustrations in this study to Dr. Joseph L. Scianni, Artist, University of Tennessee Pathological Institute.

1. McFarland, Joseph: Ganglioneuroma of Retroperitoneal Origin, Arch. Path. 11: 113 (Jan.) 1931.

2. Bigler, J. A., and Hoyne, Archibald: Ganglioneuroma: Report of Two Cases with Review of Literature, Am. J. Dis. Child. 44: 1552 (June) 1932.

Loretz<sup>3</sup> reported the first instance in 1870. Since then ganglioneuromas have been reported as arising in the central nervous system, cranial nerve roots and their associated ganglions and the sympathetic ganglions of the neck, thorax and abdomen. They also may arise in the adrenal medulla, the carotid gland, the coccygeal gland and Zuckerkandl's organ. No previous report has been found of a ganglioneuroma arising in the ovary.

Ganglioneuromas appear to arise chiefly from the sympathetic nervous system. In the ovary, groups of sympathetic ganglion

Fig. 2.—Section of ganglioneuroma of the ovary,  $\times 300$ . The stroma is very loose and rich in serum, with numerous delicate capillaries. The cells vary in size and shape, consisting of ganglion cells, polymorphonuclears and plasma cells. On the right, above and below are nerve fibers composed of pale, fine, wavy fibrils with elongated fusiform nuclei.

cells occur normally in the medulla near the hilus. Ewing<sup>4</sup> suggests that in cases presenting ganglioneuroma there is some "embryonal disturbance of the structure of the sympathetic nervous system, with the presence of superfluous undifferentiated tissue in localities giving origin to the tumors." This view is favored by their appearance so frequently in early life or as congenital tumors and by the fact that they are frequently multiple. That some of these tumors may begin as undifferentiated or embryonal types and later differentiate into a more adult type of ganglioneuroma is evident from the case reported by Cushing and Wolbach.<sup>5</sup>

A ganglioneuroma is usually a firm, circumscribed, nodular pale tumor which may be small or large. The microscopic appearance is distinguished by the presence of characteristic adult ganglion cells with their processes. The proportion of neurofibrils present is variable.

#### REPORT OF CASE

**History.**—R. B., a Negro girl aged 4 years, was admitted to the surgical service of Dr. F. W. Smythe at the John Gaston Hospital, April 11, 1935, because of painful swelling of the abdomen which had been noted for three weeks. This had become progressively worse and for two days before admission was accompanied by an edematous swelling of the legs.

Physical examination showed that the child was normally developed and well nourished. The abdomen was distended and occupied by a freely moving mass extending out of the pelvis to a level just above the umbilicus. The mass was fairly firm and smooth but with palpable depressions on one edge. It was not tender. Roentgenographic studies indicated that the mass was not associated with the kidney or intestine. The other physical changes were noncontributory.

Roentgen irradiation with 1,500 roentgens within nine days was given. Laparotomy was then performed and the mass excised, along with the attached right ovary and the fallopian tube. An uneventful convalescence followed.

**Pathologic Report.**—The specimen consisted of a lobulated, soft mass weighing 200 Gm., covered with tunica albuginea. Along its summit ran the fallopian tube. On section the tissue was everywhere yellow-pink, juicy, translucent, very vascular, extremely soft and easily picked away (fig. 1).

Microscopic examination showed a thin peripheral layer of ovarian tissue. Underlying this the normal ovarian structure was completely replaced by a tissue whose stroma was very loose and for the most part appeared to be composed of serum. There were many delicate capillaries. The cells varied in size and shape, but the general type was a large multipolar cell with a basophilic, finely granular cytoplasm. The nucleus was large, round or oval, light staining and reticulated and had in it a large, prominent, densely staining nucleolus. The typical cell was tripolar, with processes from its poles, some of which could be followed for short distances into the stroma. These cells bore a striking resemblance to a typical ganglion cell. A large proportion of these larger cells were multinucleated;

Fig. 3.—Section of ganglioneuroma of the ovary,  $\times 725$ , center of figure 2. Scattered loosely through the fluid-filled, practically fibrous tissue-free stroma are large multipolar ganglion cells with basophil, finely granular cytoplasm and large, round or oval, light staining and reticulated nuclei with large, prominent, densely staining nucleoli. A typical tripolar ganglion cell with processes from its poles can be seen in the center, and a delicate capillary on the left below. Several ganglion cells contain two or three nucleolated nuclei. Plasma cells and polymorphonuclear leukocytes are also seen.

the majority contained two well formed nucleolated nuclei as described at opposite poles of the cell or beside one another. Some of the cells contained three nuclei. The variations in the cells consisted in the amount and shape of the cytoplasm,

3. Loretz: Ein Fall von gangliösen Neurom, Virchows Arch. f. path. Anat. 49: 435, 1870.

4. Ewing, James: Neoplastic Diseases, ed. 3, Philadelphia, W. B. Saunders Company, 1928, p. 471.

5. Cushing, H. S., and Wolbach, S. B.: Am. J. Path. 3: 203 (May) 1927.

but the nuclei were essentially the same. The cell shapes ranged from round ones the size of a large mononuclear with one process to fat fusiform ones with a process at each end. Some of the cells showed a single large vacuole in the cytoplasm. A number of the larger cells showed a single, large, pink staining hyaline droplet in their cytoplasm, or the whole cell body was filled with hyaline droplets ranging in size from that of a large red blood cell to fine droplets. An occasional mitotic figure was found in a ganglion cell. The cells were either scattered loosely and indiscriminately through the fluid-like stroma or were massed in large poorly demarcated clumps. In the center of these larger denser fields some pale, fine, wavy fibrous bundles with wavy, elongated, deep staining fusiform nuclei were present. These bundles were frayed at their ends and suggested nerve fibers. The section was practically free of fibrous tissue. A striking feature of the whole section was the presence of large numbers of plasma cells and mature polymorphonuclear cells, about equal in number, which were indiscriminately infiltrated throughout the section with no suggestion of clumping or localization (figs. 2 and 3).

## SUMMARY

A ganglioneuroma of the ovary occurring in a Negro girl aged 4 years consisted of adult ganglion cells and fibrils mixed with some less differentiated elements. No previous report of a ganglioneuroma of the ovary has been found in the literature.

## TRAUMATIC THROMBOSIS OF DEEP PALMAR VEIN

MONICA HARDEN SNYDER, M.D.

AND

WILLIAM H. SNYDER JR., M.D.  
HOLLYWOOD, CALIF.

There has been a good deal of literature devoted to injuries to the hand and their economic significance in industry. Discussions of infections, injuries to tendons and nerves and fractures form the bulk of the articles, but reports of injuries to blood vessels appear from time to time. There have been

several cases of aneurysm<sup>1</sup> reported and one case of thrombosis of the ulnar artery<sup>2</sup> following a blow.

No case of traumatic thrombosis of the deep veins of the palm of the hand could be found in the literature, so we felt it worth while to report such a case. The thrombosis was the result of a sudden severe jar at the base of the hand. A definite, firm, tender, oblong mass could be palpated at the

base of the hypothenar eminence (fig. 1). It was thought to be a ganglion or chronic tenosynovitis, but exploration revealed a thrombosed deep ulnar vein and fourth digital vein (fig. 2).<sup>3</sup>

Operative removal resulted in relief of pain in the palm and made it possible for the patient to return to work as a blacksmith within three weeks.

The patient was a man of stable temperament whose story could be relied on.

Fig. 1.—Position of palmar mass on left hand.

base of the hypothenar eminence (fig. 1). It was thought to be a ganglion or chronic tenosynovitis, but exploration revealed a thrombosed deep ulnar vein and fourth digital vein (fig. 2).<sup>3</sup>

Operative removal resulted in relief of pain in the palm and made it possible for the patient to return to work as a blacksmith within three weeks.

The patient was a man of stable temperament whose story could be relied on.

3. Toldt, Carl: *An Atlas of Human Anatomy: Anatomy of Veins of the Palm*, ed. 2, New York, Rebman Company 2: 700, 1926.

## REPORT OF CASE

A man aged 67, a blacksmith, about a month before consulting a physician was holding an anvil while it was being pounded on, and a sudden jar caused immediate pain in the palm of the left hand. Since that time he had experienced considerable pain whenever he used that hand. A mass appeared at the site of the injury soon afterward. The ring finger became so painful that he could not move it without discomfort. Pressure

Fig. 2.—Veins of palm of left hand, showing portion thrombosed.

of any kind on the palm caused pain. He padded and bandaged it but still had difficulty in using his hand. He did not stop work, however, thinking that the condition would improve of its own accord in time. After four weeks, during which time the pain made him entirely unable to carry on his work satisfactorily, he consulted a physician.

His past history and family history were entirely irrelevant. He was well nourished and well developed, appearing robust for his age. There were no conditions noted of any significance except for scars on his arms of many previous injuries incident to his work. None had been of a serious nature. On examination of the left hand, the palm at the base of the hypothenar space was tender. A mass was palpable below the surface, apparently in the muscle bundle, measuring about 1 by 2.5 cm. It was firm and movable but did not move with flexion and extension of the fingers. No surface lesion could be seen. There was slight diminution in sensation in the fourth and fifth fingers on the palmar aspect.

Dr. Steele F. Stewart, called into consultation, described the lesion as follows: "There is a small deep elastic mass near the base of the hypothenar eminence of the left hand which appeared following trauma one month ago. It is slightly tender

Fig. 3.—Thrombosed vein of hand removed at operation.

and appears to be along the tendons of the fifth finger. My impression is that it is a tenosynovitis, post-traumatic, which interferes with use of the finger and hand. I think that long rest will let it disappear but that surgery will hasten the process." The surgeon's diagnosis was "ganglion" of the left palm.

It was decided that surgery should be resorted to to put the man back to work as soon as possible.

Operation was done under local procaine hydrochloride anesthesia by injection into the median and ulnar nerves just above

the wrist and a cuff anesthesia by infiltration around the wrist. Incision was made in the palm of the left hand beginning just distal to the wrist and following the middle crease of the palm for a distance of about 3.5 cm. The palmar skin was then dissected back, the palmar fascia exposed and a mass palpated directly beneath the palmar fascia. The fourth digital nerve branching from the ulnar nerve was then exposed just beneath the fascia and dissected free from the mass. The mass was found to originate from the fourth digital vein and extended upward within the deep ulnar vein 3.5 cm. to the wrist. It consisted of a dilated vein with thrombosis. The vein was clamped and tied at both ends and removed. The subcutaneous tissues were brought together with interrupted plain catgut. The skin was closed with interrupted dermal mattress sutures. The postoperative diagnosis was thrombosis of the fourth digital vein and the deep ulnar vein in the hand.

The specimen (figs. 3 and 4) was a greatly dilated vein measuring 0.4 cm. in thickness. In its midportion there were two little nodules measuring 1 by 0.6 cm. The microscopic

Fig. 4.—Cross section of thrombosed vein of hand showing beginning organization of clot.

section showed a thickened fibrous venous wall with antemortem clot which was quite firmly adherent in places. The pathologic diagnosis was dilatation and thrombosis of a small vein.

The patient made an excellent recovery and was able to return to active duty three weeks after the operation. He is now free from pain and is using his hand normally.

#### SUMMARY

An injury resulted in thrombosis of the deep ulnar and fourth digital veins of the palm of the left hand. A small, deep, palpable, tender mass was present at the base of the hypothenar eminence. The question of prolonged rest for the cure of a chronic tenosynovitis was considered but rejected in favor of exploration. At operation a greatly dilated small thrombosed vein was removed and the patient was able to return to work soon after.

This is the first case we can find reported in the literature of traumatic thrombosis of a deep palmar vein and we hope that this presentation will be of some help in the diagnosis of similar cases in the future.

#### THE PHOTOSTETHOSCOPE

A DEVICE FOR VISIBLY DEMONSTRATING CARDIAC SOUNDS,  
ESPECIALLY FETAL HEART SOUNDS

EDWIN J. DE COSTA, M.D., CHICAGO

Knowledge of the condition of the fetus in utero is entirely dependent on observation of the fetal heart tones. Methods of observation have varied as science has progressed and made available new instruments. Fetal heart tones were first heard with the unaided ear in 1818 by Major.<sup>1</sup> It was not long before the newly invented stethoscope was also put into use. That the stethoscope itself was not a great advance is proved by the frequency with which one encounters direct auscultation, even at the present time. Later the head stethoscope was introduced, making it possible for the obstetrician to observe the heart tones without interfering with asepsis. However, at best it is an awkward, uncomfortable instrument.

With the improvement of electrical means of reproducing, transmitting and amplifying sound waves, it was inevitable that such methods should be applied to the study of adult and fetal heart sounds. In 1923 Falls and Rockwood<sup>2</sup> published a preliminary report on the use of microphonic reproduction of fetal heart tones. They employed the instrument demonstrated by Abbott at Purdue University in 1922.<sup>3</sup> In this preliminary report they mention certain difficulties encountered, most serious of which arose from extraneous noises and feed-back howls. They believed that if these difficulties could be eliminated the machine would become standard equipment in every maternity hospital. The problems they faced in 1923 are still met today, in spite of the tremendous improvement in microphones, thermionic valves and amplifying and reproducing apparatus. Electric stethoscopes are available commercially for the auscultation of adult heart tones and for the demonstration of fetal heart tones, but they are not entirely satisfactory. The most recent type of amplifying stethoscope is that described by Matthews.<sup>4</sup> In order to overcome the aforementioned difficulties, his model has become such a complicated, cumbersome and expensive piece of equipment that the author himself admits it to be unpractical even for hospital use.

The present study is concerned with the development of a simple, compact and inexpensive device that will demonstrate to the physician the condition of the baby as manifested by the heart tones. A sensitive transmitter of the crystal type and a high gain amplifier which satisfactorily amplifies fetal heart tones so that they can be heard several hundred feet away are so sensitive that the microphone picks up the sounds from the loud speaker and develops a howl. It has been impossible to filter out the feed-back and preserve simplicity and compactness. In this device the loud speaker has been eliminated entirely and a small neon lamp substituted; the device is called the photostethoscope. The photostethoscope translates sound into flickers of light and by this means reproduces the rate and regularity of fetal heart sounds quite as faithfully as the speaker. The greatest nuisance—feed-back—is eliminated.

The photostethoscope is housed in a small metal cabinet from which extend leads to the microphone and power line. The microphone, supported by sponge rubber, is attached by a wide adhesive strip to that location of the abdomen where fetal heart tones are most audible. Electrical connection is established through any wall plug. The gain control (A) is then adjusted to attain the degree of amplification necessary to operate the indicating bulb (B). Either the first or the first and second fetal heart sounds may be demonstrated as flickers of light by varying the gain adjustment.

The microphone, on its rubber cushion, causes no discomfort to the patient. During labor it need not be in constant applica-

3. Abbott, R. B.: Eliminating Interfering Sounds in a Telephone-Transmitter Stethoscope, *Physiol. Rev.* 21: 200 (Feb.) 1923. Keiper, G. F.: A Multiple Electrical Stethoscope for Teaching Purposes, *Correspondence*, *J. A. M. A.* 81: 679 (Aug. 25) 1923.

4. Matthews, H. B.: The Continuous Auscultation of the Fetal Heart by Means of an Amplifying Stethoscope, *Am. J. Obst. & Gynec.* 34: 898-899 (Nov. 1937).

tion but can be held against the abdomen as frequently as desired. During delivery the microphone remains constantly in place and in no way interferes with the aseptic technic.

There are some minor defects. Strong uterine contractions interfere with the operation of the apparatus for the duration of the pain, but with relaxation the heart tones are again demonstrable. Fetal movements and shifting of the linen produce arrhythmic flickers of light; slight changes in the draping technic will minimize the disturbance from this source. Extraneous sounds, caused by walking or talking in the labor room, interfere only when they are loud, but crying or snoring by the patient creates a more serious annoyance. The vibration is apparently transmitted through the delivery table to the microphone. This annoyance can be greatly reduced by using a sponge rubber mattress on the delivery table and securing the cooperation of the patient. The most serious source of interference is from unshielded, high voltage x-ray equipment. Proper shielding and grounding of such x-ray apparatus constitute the only satisfactory method of eliminating such disturbance.

It is safer to install the amplifying unit outside the delivery room when gaseous anesthetics are used. For this the microphone cord can be lengthened and the indicating lamp may be mounted in the delivery room. There is nothing in the amplifier to spark or arc, but a breakdown of the condenser might be a hazard.

These objectionable factors are not always present. In any event they are outweighed by the positive advantages. The facility of application of this instrument encourages its frequent use. The continuous portrayal of fetal heart tones presents constant information concerning the condition of the fetus. With such information available, failure to recognize imminent intrapartum death should occur less frequently.

The photostethoscope may prove useful in the study of abnormalities of the adult heart. Enough work has been done to indicate definite light patterns associated with murmurs and the various arrhythmias. It affords a new avenue of approach for studying the heart and provides an additional method of demonstrating cardiac action to students.

#### SUMMARY

The photostethoscope is a practical, efficient and inexpensive device for demonstrating fetal and adult cardiac sounds. It was designed for the continuous observation of fetal heart tones during second stage labor and delivery. Fetal distress can be promptly detected by its use.

### EVALUATION OF THE INJECTION TREATMENT OF HERNIA

A STATISTICAL AND ANALYTIC STUDY

CLINICAL LECTURE AT SAN FRANCISCO SESSION

FRANKLIN I. HARRIS, M.D.

AND

ALFRED S. WHITE, M.D.

SAN FRANCISCO

The treatment of hernia by injection has been a controversial subject for over a hundred years. Until recently there was an overwhelming skepticism as to the safety and value of this method. In the last five years this skepticism has been replaced by an enthusiasm which has resulted in its widespread use. Optimistic reports have appeared similar to those of the late Ignatz Mayer<sup>1</sup> of Detroit and Franz Wyss<sup>2</sup> of Switzerland, who claimed a cure in 96 per cent of their cases by the injection method. Bratrud,<sup>3</sup> McKinney,<sup>4</sup> Rice<sup>5</sup> and McMillan and Cunningham<sup>6</sup> reported cures in from 83 to 92 per cent of their cases. In contrast to such results, Burdick and Coley<sup>7</sup> of New York submitted statistics showing unsuccessful results in 96 per cent of their cases. Many surgeons when interviewed emphatically state, without quoting any personal experience, that the injection method is theoretically unsound and unsafe and from the practical standpoint is worthless in the treatment of hernia.

An endeavor to evaluate this method was approved by the research committee of the Mount Zion Hospital, San Francisco, in February 1934. A planned and systematic investigation of the treatment of hernia by the introduction of irritant chemicals into fascial planes was begun. Experimental animals were used for study of the reactions of the proliferative tissue to various solutions, and the biochemical properties of such solutions were critically analyzed. A scientific study of the construction and application of trusses was made, and a special hernia clinic was established in the outpatient department. A careful, detailed recording and follow-up system was instituted, from which 23,000 items were analyzed for this report. We treated the patients ourselves. All clinical observations were made with the attitude of comparing the results with those for years obtained with our operative treatment of rupture.

During the past few years we have submitted progressive reports of this work.<sup>8</sup> It is our purpose in this paper to present certain definite conclusions which

we believe will reconcile the wide divergence of opinion which has existed as to the value of the injection method of treating hernia.

From 1933 to 1938, 573 patients with hernia of all types have presented themselves for treatment (table 1). Of this number 236, or 41 per cent, were treated by the injection method, ninety-one, or 16 per cent, by operation, and 246, or 43 per cent, by the

application of trusses. Only 41 per cent of the cases could be utilized for this clinical investigation, despite the fact that in this especially established clinic for the study of the injection method we tried to treat as many patients as possible by this means. An analysis of the remaining 59 per cent of the cases shows the limitation of the possible application of this procedure (table 2).

From a study of table 2 it may be seen that in 6.6 per cent of the cases injection could not be considered because of lack of complete reducibility of the hernia, that in 9.6 per cent of the cases it could not be contemplated because of inability to fit a satisfactory truss, that 9.4 per cent of the patients preferred operation as an easier method of treatment and that 6.8 per cent of the patients were considered unsuitable for this method because of infirmity, old age or poor tissues. It is interesting that the mechanical method of relieving rupture by the simple application of a retaining truss was sufficient to satisfy the needs of 26.6 per cent of the patients referred to this clinic. In this paper we are interested primarily in a study of the 236 cases in which treatment was by the injection method.

The first conclusion derived from our experience is that this method of treatment has not been responsible for a single death. The complications which have occurred have been reported in detail elsewhere.<sup>9</sup> There has been no atrophy or sloughing of the testicles and no peritonitis or formation of abscess. No impotence has resulted. Complications such as transient swelling of the cord, hydrocele of the cord, epididymitis, tran-

sient shock due to intraperitoneal injection of the solution and dermatitis of the skin under the truss pad have all been of minor significance and have not required hospitalization in any case. Even these complications were noted mainly in our early experience.

We are convinced that in the hands of experienced surgeons familiar with the principles and technic the injection method is absolutely safe and devoid of serious complications. We are convinced that there is a place for this method in the treatment of hernia. We are also convinced, however, that the end results are not comparable to those obtained with surgical procedures. We are convinced that many of the published enthusiastic reports have not been subjected to sufficient critical analysis and follow-up. We believe that it is of the utmost importance to publicize to the medical profession and to the public exactly what can be expected in the way of permanent cures from the injection method.

We define a cure of a hernia as the complete absence of the protrusion on examination as well as the absence of any bulge in the musculature on straining. A cure also implies that the patient has no need to wear a mechanical device such as a truss. On the basis of this definition our figures show that 134 patients, or approximately 57 per cent of the total of 236, can be said to be cured. These patients have been examined from six months to three years after the removal of the truss

(table 3). Sixty-six patients, or 28 per cent, are listed as possibly cured. By this we mean that they are still wearing a truss, either because we advised them to or because they do not feel sufficiently secure to go without one. In this group there is no objective evidence of hernial protrusion, but the result can be classified only as a possible cure. The treatment of thirty-six patients

9. Harris, F. I., and White, A. S.: Injection Treatment of Hernia, *Am. J. Surg.* 37: 263 (Aug.) 1937.

has been classified as a complete failure, by which we mean either that we have been unable to obtain an initial closure or have been unable to cure a recurrence. This gives a percentage of complete failures of approximately 15. Table 4 contains a detailed statement of these figures according to the type of hernia.

This figure of 15 per cent failures, which represents our final figure to date, does not give a true picture of

the actual recurrences. We found that many hernias remained closed for from six to eighteen months and then recurred (table 5). These hernias were those which early in our experience seemed to be closed after a few injections and were considered cured. The fallacy of discontinuing treatment on this basis was seen when frequent recurrences developed. This may explain the poor end results reported by surgeons who have not treated their patients over a sufficient period of time. The total number of such recurrences was seventy-nine, giving an immediate recurrence rate of 34 per cent. When further courses of treatment were given, fifty-six of the hernias were finally closed and are now included among those cured, while the remaining twenty-three were added to the list of complete failures. Thus an initial recurrence rate of 34 per cent was reduced to a final figure of 15 per cent failures by persistent retreatment.

The difficulties met in this form of treatment and the reasons for the recurrences and failures are illustrated by table 6. We note that most of the recurrences can be attributed to errors in technic, such as insufficient treatment or improper fitting of the truss. The final figure of thirty-six failures represents the minimum of failures due to the inherent inadequacy of the method.

Failure by the injection method does not preclude the possibility of cure by operative means or palliative treatment by truss wearing. Table 7 shows the final disposition of our failures, and it may be pertinent to note that operation on patients previously treated by injection has not in our experience been technically difficult. It is true that at operation there is some distortion of the usual lines of cleavage in the inguinal region, and a varying amount of fibrosis may be found.

Our operative experience in such cases has confirmed our experimental work on animals and has convinced us that the injection of irritant chemicals does produce binding adhesions between muscle and fascia.

In previous papers<sup>10</sup> we emphasized the fact that our patients with hernia were divided into two main groups, the good risk group and the poor risk group. In all fairness to the injection method we must analyze our figures again from this point of view. The good risk group is composed of patients who are good surgical risks; they are mainly under 50 or if over 50 have no serious organic disease that contraindicates operation. The poor risk group is composed largely of patients over 50 in poor general physical condition, and in our opinion its members were definitely never safe surgical risks (table 8).

There were, in the total series of 236 patients, 136 good risks. In this group 108, or 79.5 per cent, were cured; there were eleven, or 8 per cent, possible cures and seventeen, or 12.5 per cent, definite failures. In the poor risk group of 100 patients there were 26 per cent of cures, 55 per cent of possible cures and 19 per cent of definite failures. Despite the apparent small percentage of cures in the latter group, the general improvement in the comfort of the patient by reduction in the size of the hernia or by its complete elimination after the injection treatment makes the results satisfactory even though continued truss wearing is necessary.

Certain definite factors influence the results obtained. An analysis of table 9 shows that the relation of cure to the age of the patient is significant. The young patient has a better outlook for cure by the injection method than the older patient. This confirms the excellent results we recently reported in the treatment of hernia in children by the injection method.<sup>11</sup>

The length of time the hernia has existed (table 10) is also of considerable importance. The older the hernia the less chance of curing it, although there is

an excellent outlook for improvement to the point of possible cure.

The length of the inguinal ligament, which heretofore has been entirely overlooked in the differential diagnosis of the types of inguinal hernia, is likewise of primary importance. In our early investigations we

10. Harris, F. I., and White, A. S.: The Injection Treatment of Hernia: Its Present Day Status, California & West. Med. 45:391-395 (Nov.) 1936; Injection Treatment of Hernia, Proceedings of the Pan Pacific Surgical Association, July 1937.

11. Harris, F. I., and White, A. S.: The Injection Treatment of Reducible Inguinal Hernia in Children, Arch. Pediat. 54:665 (Nov.) 1937.

found that it was of the utmost necessity in injection therapy in contrast to operative treatment to make an exact differential diagnosis of the type of inguinal hernia. Our studies led to the development of certain definite differential points which heretofore have not been described. Most important of these points is the length of the inguinal ligament as measured from the anterior-superior spine to the spine of the pubis. In

a previous communication<sup>12</sup> it was shown that when the inguinal ligament measured less than 13 cm. the hernia was always of the pure indirect type, whereas when the length approximated 15 cm. the hernia was often found to be a combination of the indirect and the direct type. When the inguinal ligament was over 15 cm. the hernia was always of the pure direct type. Table 11 shows that the average length of the inguinal ligament in the cases in which cure resulted was 13 cm., whereas the average length in cases of possible cure and of failure was 15.2 cm. This shows the prognostic significance of the length of the inguinal ligament in the treatment of hernia by injection. Our unpublished studies lead us to believe that this measurement is of similar prognostic value in the operative cure of hernia.

With the foregoing figures and facts in mind, an evaluation of the injection method in unselected cases of hernia can be made as follows (table 12): With pure indirect inguinal hernia there is an 80 per cent chance of cure; with combined indirect and direct inguinal hernia there is only a 37 per cent chance of cure, while with pure direct inguinal hernia there is only a 30 per cent possibility of cure. Recurrent postoperative inguinal hernias show 22 per cent of cures. Reducible umbilical hernias in our experience have shown a 100 per cent chance of cure. These umbilical hernias were mainly in young children. Femoral and most incisional hernias are totally unsatisfactory for treatment by this method.

TABLE 11.—Length of Inguinal Ligament in Relation to End Results

100 dispensary visits. For these reasons it is not practical from an economic standpoint to recommend this method in compensation cases.

Considerable discussion and confusion exist as to certain salient points in the technic of the treatment. The importance of the chemical solution used has been overemphasized, largely because of commercial advertising. It has been our experience that many excellent,

12. Harris, F. I., and White, A. S.: Length of the Inguinal Ligament, J. A. M. A. 109: 1900 (Dec. 4) 1937.

properly prepared solutions are commercially available. In general they may be divided into two classes, those containing tannic acid in alcohol and those containing a fatty acid base. Experimental and clinical investigations have shown little difference in the fibrosis produced by the two types.<sup>13</sup> The fatty acid solutions have the practical advantage of a somewhat more simple

and is usually sufficient to satisfy a patient who has had two or three operative experiences.

If the object of the treatment is to offer the patient a possible cure or improvement with continued truss wearing, the field of usefulness of the injection method can be considerably extended. Many patients have hernias that produce symptoms but are denied operation because of their poor general condition. The injection method should be welcomed by surgeons as a valuable means of treating such patients.

Our experience has satisfied us that the prejudices against the injection method have been founded on theoretical misconceptions. On the other hand, the unwarranted enthusiasm for the method has been founded on reports of surgeons who have used the procedure but have failed to follow up critically their end results. The statistics presented in this paper offer an appraisal of the possibilities of the treatment of hernia by injection.

SUMMARY AND CONCLUSIONS

To evaluate the injection treatment in a study of 573 cases of hernia of all types, only 41 per cent, or 236 cases, could be utilized.

No serious complications or deaths occurred.

The 236 patients treated by injection have been followed up for from six months to three years after the completion of treatment. There were 57 per cent of cures, 28 per cent of possible cures and 15 per cent of complete failures.

This method of treatment if the object is cure should be limited to a small group of patients with pure indirect inguinal hernia. This group consists of young persons with recent hernial development whose inguinal ligament measures about 13 cm.

Reducible umbilical hernia in children can also be cured by the injection method.

The field of usefulness of the injection method can be considerably extended if the object is possible cure with continued truss wearing.

Recurrent postoperative inguinal hernia should be given a trial treatment by the injection method.

TABLE 14.—Number of Office Visits per Patient

Office Visits per Patient		Length of Time of Active Treatment	
Number of Patients	Number of Office Visits	Number of Patients	Number of Months of Active Treatment Not Counting Follow-Up
7	6-10	180	1-6
125	10-20	36	6-12
66	20-30	12	12-18
38	30-102	8	18-40
236		236	
Average number of office visits, 23		Average length of time of active treatment, 5.1 months	

This method of treatment is not simple and necessitates detailed care over a considerable period.

The most important single factor in the technic is the selection and application of a truss.

In general, the end results of the treatment of hernia by injection are not comparable to those obtained by operation. These results, however, are sufficiently good to recommend this treatment when operation cannot be considered because of economic, personal or physical reasons.

450 Sutter Street—516 Sutter Street.

TABLE 13.—Possibilities of Treatment in Selected Cases of Good and of Poor Risks

Type of Hernia	Approximate Result in Cases of Good Risks	Approximate Result in Cases of Poor Risks
Pure indirect inguinal.....	87% cures — wearing truss 13% failures	53% cures 43% wearing truss 4% failures
Combined indirect and direct inguinal	79% cures 11% wearing truss 11% failures	26% cures 60% wearing truss 14% failures
Pure direct inguinal.....	58% cures 33% wearing truss 9% failures	10% cures 62% wearing truss 29% failures
Recurrent postoperative inguinal	50% cures 41% wearing truss 9% failures	— cures 58% wearing truss 42% failures

application. The solutions used in the treatment of varicose veins are definitely dangerous and contraindicated in this technic.

Probably the most important single factor contributing to a successful result is the application of a scientifically correct truss. The importance of this far outweighs the value of any one solution over another. The selection and application of the truss necessitate accurate differential diagnosis of the type of inguinal hernia and require individual judgment for each patient. Probably the greatest obstacle to the popularization of this method lies in the general lack of knowledge on the part of surgeons of the principles of the construction and fitting of trusses.<sup>14</sup> It is our firm conviction that there can be no successful treatment of hernia by injection unless the patient is fitted with a proper truss.

Summing up our experience briefly, we believe that, if the object of treatment is cure, the injection method should be limited in its use to selected patients with pure indirect inguinal hernias. They should be young patients who are good risks, with recent hernial development, whose inguinal ligaments measure about 13 cm. Umbilical hernias in children offer an excellent field for this method. For persons who are good risks but whose inguinal hernia is of the combined indirect and direct type or the pure direct type, the results, while definitely not as favorable as those obtained with surgical methods, are sufficiently good to warrant recommendation of injection treatment when, for economic or personal reasons, operation is not possible. However, such patients should be made fully cognizant of the fact that the possibility of cure is less with the injection method than with operation. Recurrent postoperative inguinal hernias, which so often are the bane of the surgeon and the patient, are well worth treatment by this means. For, even if a cure is not obtained, improvement to the point of comfortable truss wearing can be promised

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS.      HOWARD A. CARTER, Secretary.

SUPER FISCHERTHERM, MODEL 114-A-3  
ACCEPTABLE

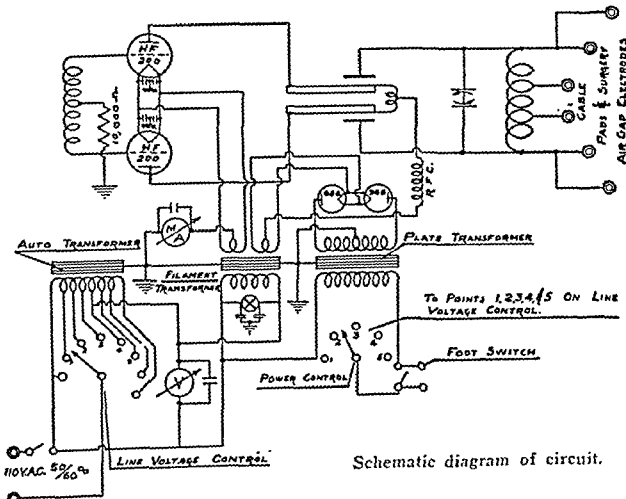

Manufacturer: The Fischer Corporation, 673 Ivy Street, Glendale, Calif.

The Super Fischertherm Short Wave Diathermy Unit, Model 114-A-3, is recommended for medical and surgical use in the office or hospital. This unit is similar to the Council accepted Super Fischertherm Unit, Model 114-A (THE JOURNAL, Dec. 18, 1937, p. 2064) except for the addition of higher powered tubes with necessary wiring changes and increased output, according to the firm. The cabinet housing is the same for the two units. Standard equipment includes inductance cable, cuff and pad electrodes and surgical accessories for coagulation, desiccation and cutting purposes. Air spaced electrodes and supporting arms are optional. No evidence was submitted concerning the ability of the unit to supply deep heat with air-spaced technic.

Super Fischertherm 114-A-3.

The circuit consists of two vacuum power tubes and two rectifier tubes in a simple arrangement. The output circuit is tuned by a split stator condenser. In adjusting for line voltage, an ohmite tap switch and a variable condenser resonance control are used. The newer model, 114-A-3, employs HF-300 Amperex tubes instead of HF-200 tubes. This change in tubes makes it necessary to use one more turn in the tank coil and slight change in filament voltage; i. e., 12 volts now delivered by filament transformer.

Schematic diagram of circuit.

The firm submitted the following physical data: When the machine was operated continuously for two hours at full load, the power input was approximately 1,990 watts. The average high frequency power output was 762 watts as measured by the calorimeter method. No part of the machine was unduly hot after the two hour run.

These data were later substantiated by tests made for the Council. The transformer temperature rise and the rise at various levels within the cabinet were within the limits of safety prescribed by the Council. The final temperature of the transformer when operating on lamp load of 520 watts was 79 C. The input was 1,540 watts. Burns may occur with this unit as with other short wave units but are less likely to occur than with conventional diathermy. A filter to inhibit feed-back of radio frequency current into the power line is included in the equipment.

In order to substantiate heating claims made for the unit, the firm submitted tests performed at a reliable laboratory. Four healthy male medical students served as subjects for these tests. Eight experiments each were performed with the inductance cable, cuff and pad technics. Temperature measurements were made with the thermocouple in the anterior portion of the thigh at depths of one-eighth, three-fourths and 2 inches or on the bone. These depths were measured from the skin straight in; that is, normal to the surface of the skin. The technic employed in the measurements was that recommended by the Council on Physical Therapy.

In applying the inductance cable approximately 1½ inches of bath toweling was wrapped around the thigh and held in place

Average of Eight Observations

Deep Muscle		Subcutaneous		Skin		Oral	
Initial	Final	Initial	Coil Final	Technic Initial	Final	Initial	Final
98.5	106.9	97.1	105.6	93.9	101.7	98.4	99.5
97.9 106.0		95.9 106.5		93.5 102.7		98.2 99.4	
98.4 104.1		97.2 102.3		93.9 99.7		98.4 99.1	

by approximately four wraps of the inductive cable. The averages for eight observations with this technic are given in the accompanying tables.

These data were accepted by the Council. The unit was investigated clinically for the Council and reported to function satisfactorily.

In the advertising copy submitted, the output is stated to be 762 watts as measured by the calorimeter method. That the physician may compare this value with the value obtained by the commonly used method, the Council lamp load output of 520 watts is also given.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Super Fischertherm, Model 114-A-3, for inclusion in its list of accepted devices.

O. E. M. FACE TENT WITH  
OXY-ATOR ACCEPTABLE

Manufacturer: Oxygen Equipment Manufacturing Company, Inc., 247 East Fifty-Sixth Street, New York.

The O. E. M. Face Tent is recommended for intermittent oxygen therapy administered to conscious and cooperative patients. It is a boxlike mask, made of transparent plastacele (cellulose acetate) which forms a projection over the patient's nose, mouth and chin and is open at the bottom. It may be fitted to any adult face by molding the pliant aluminum framework. This is wrapped in moleskin. Malleable aluminum ear pieces, with loops at the ends, hold it in place. Tapes that tie back of the head may be used for the same purpose.

O. E. M. Face Tent with Oxy-Ator

In conjunction with the face mask, an Oxy-Ator is supplied to increase the efficiency of the equipment. This device attaches directly to the regulator. As oxygen is administered (in any flow from 6 to 12 liters per minute) the Oxy-Ator draws air into the circuit from the outside atmosphere, forming an air-oxygen mixture.

Oxygen is supplied by means of this rubber tubing, perforated on the portion inside the mask to direct the flow upward toward the center of the nostril. During expiration, oxygen collects in the mask and is forced out through the opening at the bottom. It is dry when admitted, since it has not passed through the water bottle. However, the firm claims that enough moisture from the exhaled air remains in the mask to provide a certain amount

of humidity. According to the firm, there is an almost immediate build-up of oxygen concentration in the face tent. The firm believes that additional cooling is not necessary if a continuous flow of 4 or more liters of oxygen is employed.

The unit was investigated clinically in the following manner:

The face tent and Oxy-Ator were used as directed and certain oxygen concentrations were obtained. The samples taken from patients and normal subjects were obtained with a small catheter from the oral pharynx at the end of forced expiration. The presence of carbon dioxide concentration approaching 4 to

*Analyses of Oxygen-Air Mixtures from Tube  
Connected to Oxy-Ator*

Rate of Oxygen Flow on Gage	Oxygen	Increased Rate of Flow Due to Air Added Through Oxy-Ator
4 liters oxygen per minute.....	92%	4.4 liters per minute
6 liters oxygen per minute.....	87%	7.1 liters per minute
8 liters oxygen per minute.....	86%	9.6 liters per minute

5 per cent is an indication that one has a sample of alveolar air. Of course, the oxygen percentages in this case are approximately 4 per cent less than the concentration that enters the lungs. This carbon dioxide determination has nothing to do with rebreathing of carbon dioxide from the mask. These analyses were determined on samples taken with the Oxy-Ator set to pick up the maximum amount of air.

CASE 1.—Normal healthy adult male with mask carefully fitted to face, subject sitting:

Oxygen Flow	Oxygen	Carbon Dioxide
4 liters per minute.....	25.6%	4.6%
6 liters per minute.....	33.0%	4.8%
8 liters per minute.....	48.8%	4.8%

The mask on the same subject was readjusted and the delivery tube changed so that it directed gas onto the upper lip in front of the nose:

Oxygen Flow	Oxygen	Carbon Dioxide
4 liters per minute.....	37.6%	4.8%
6 liters per minute.....	47.2%	4.8%
8 liters per minute.....	54.4%	4.6%

Comments: With a flow of 6 liters per minute, the mask was comfortable for a period of two hours. There was some tendency toward drying of the nasal mucous membranes. There was no clinical evidence of accumulated carbon dioxide as judged by observation of breathing. Analysis for carbon dioxide of samples taken during inspiration showed carbon dioxide from 0.2 to 0.4 per cent.

CASE 2.—Woman with hypertensive heart disease, decompensated, using the face tent and Oxy-Ator:

Oxygen Flow	Oxygen	Carbon Dioxide
6 liters per minute.....	68.8%	3.4%
8 liters per minute.....	76.0%	3.2%

These analyses were checked twice. This was the highest oxygen concentration obtained at any time.

CASE 3.—Patient dyspneic from pulmonary infarct and cardiac failure:

Oxygen Flow	Oxygen	Carbon Dioxide
6 liters per minute.....	43.8%	3.8%
8 liters per minute.....	58.0%	4.0%

This patient complained of the mask being too warm. Eight liters per minute was required to give him any relief.

This mask is useful, in the opinion of the Council, for the intermittent type of oxygen therapy. It can be kept on the face if the patient is quiet, conscious and cooperative. When properly

fitted to the face, it delivers a high concentration of oxygen in most cases but is variable in efficiency depending on the type of breathing and how it is applied to the face. The use of a device such as the Oxy-Ator appears to increase the efficiency of the face mask. However, a 6 liter flow of the air-oxygen mixture is necessary to eliminate the accumulation of carbon dioxide in the mask when used with Oxy-Ator. The hazard of very high oxygen concentration used over long periods of time must not be overlooked.

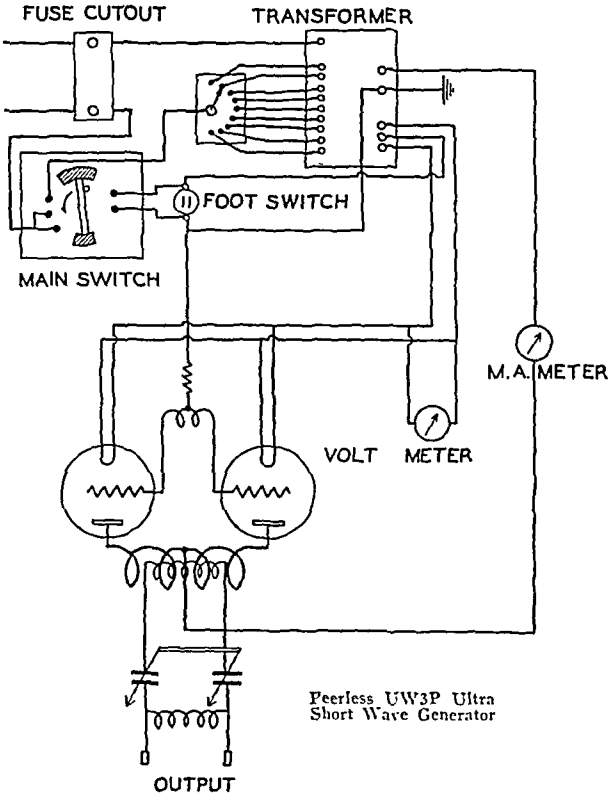

In view of the foregoing report, the Council on Physical Therapy voted to accept the O. E. M. Face Tent and the Oxy-Ator for inclusion in its list of accepted devices.

**PEERLESS ULTRA SHORT WAVE UNIT,  
MODEL UW3P, ACCEPTABLE**

Manufacturer: Peerless Laboratories, Inc., 115 East Twenty-Third Street, New York.

The Peerless Ultra Short Wave Unit, Model UW3P, is recommended for medical and surgical use. Pads, cuffs, inductance coil, treatment arms for air-spaced electrodes and metal electrodes are part of the standard equipment. Surgical accessories for cutting, desiccation and coagulation are available on request. The shipping weight of the machine is approximately 105 pounds.

Operating at a wavelength of 6 meters, it employs a two tube push-pull oscillating circuit. One branch of the patient's circuit

is inductively coupled and the other is capacitatively coupled to the oscillating circuit. The two branches of the patient's circuit are tuned simultaneously by means of a double condenser with parallel plates. A switching arrangement incorporated in the machine provides correct operating voltages to filament, plates and grids regardless of line voltage variations within a range of from 105 to 135 volts in a parallel line.

The unit has an input of approximately 700 watts. The output, as measured by lamp load, photoelectric cell and wattmeter, is approximately 325 watts. Temperature rise of the transformer and at various levels within the cabinet when operated at full load for approximately two hours was within the limits

prescribed for safety. The unit is licensed by the Electrical Research Products Corporation. Filters are to be included to prevent radio interference.

In addition, evidence was submitted by the firm to substantiate claims made for the heating ability of the unit when applied to the living human thigh. A reliable investigator performed tests with air-spaced electrodes. The technical procedure for making the tests was that recommended by the Council on Physical Therapy. Air-spaced circular electrodes, with average diameter

*Average of Six Observations, Air-Spaced Technic*

Deep Muscle Temperature		Oral Temperature	
Initial	Final	Initial	Final
99.1	104.7	98.7	98.9

of 4½ inches, were placed approximately 1¾ inches from the skin and 10 inches apart center to center. Six observations on the air-spaced technic only were given consideration and the averages are shown in the accompanying table.

The apparatus was subjected to clinical study by a reliable investigator, who tried it with air-spaced electrodes and reported that it gave satisfactory service.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Peerless Ultra Short Wave Unit, Model UW3P, for inclusion in its list of accepted apparatus.

### SANDERS VASOCILLATOR ACCEPTABLE

Manufacturer: American Hospital Supply Corporation, 1086 Merchandise Mart, Chicago.

The Sanders Vasocillator or Sanders Bed (as it was formerly called) is designed to aid circulation in peripheral vascular diseases by changing the posture of the patient at regular intervals. In appearance, the Vasocillator looks like an ordinary bed, consisting of an iron frame with coil springs supporting a felt mattress. The frame is mounted on a cradle and is geared to operate through an arc adjustable from 10 to 24 inch swings

*Sanders Vasocillator.*

(as measured at the head of the bed in relation to the floor) so that each end of the bed may be alternately high, in midposition or low. If desired, the bed may be held stationary at any desired angle. The oscillating mechanism, powered by a quiet motor, may be regulated according to the prescription of the physician. Its period of oscillation can be adjusted to take from one to seven minutes for a complete

cycle. The physician, the nurse or the patient may regulate the time to complete each cycle at will. The patient may lie flat or with the knees and feet elevated in relation to the body.

The Vasocillator is recommended by the firm for the treatment of peripheral vascular diseases such as threatened gangrene of diabetic or arteriosclerotic origin and of thrombo-angiitis obliterans without extreme capillary stasis (Buerger's disease).

Investigated in a clinic acceptable to the Council, the bed appeared to be a useful adjunct in the treatment of a limited number of peripheral vascular diseases due to capillary stasis, particularly in giving exercises similar to Buerger's exercises to individuals unable to perform active movements. The patients learn to sleep in the bed, thus continuing the exercise over long periods including day and night.

In the opinion of the Council, this bed has a limited therapeutic usefulness and no more can be expected from it than can be achieved by the conventional Buerger exercises. The Council points out that this oscillating bed is indicated for use in conjunction with other methods of treatment.

In view of the foregoing report, the Council voted to accept the Sanders Vasocillator for inclusion in its list of accepted apparatus.

## Council on Pharmacy and Chemistry

### REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.  
PAUL NICHOLAS LEECH, Secretary.

### VI-VEX NOT ACCEPTABLE FOR N. N. R.

Vi-Vex, manufactured by the Vi-Vex Manufacturing Company, Washington, D. C., was presented to the Council for consideration, with the information that the product consisted of 2 grains of phenacetin, 5 grains salicin, and ¼ grain caffeine citrated. The product is claimed to be relief for colds, grip, headaches, sinus and neuralgia if used "as prescribed by your physician or by the directions."

Such a product is in conflict with the rules of the Council; it consists of an unoriginal and also irrational mixture of well known drugs whose actions are also well known; the proprietary name is unwarranted and gives no information as to the composition of the product.

Vi-Vex is not a relief for all cases of colds, grip, headaches, sinus infection and neuralgia, and the advice on the label that if the case has progressed "take one every four hours" is an invitation to indiscriminate self medication. There is no reason why acetophenetidin should be combined with salicin (a salicyl preparation) in fixed proportions. If a physician desires to give an antipyretic combined with citrated caffeine it is his duty to prescribe it in the proportion indicated by the individual case.

The Council declared Vi-Vex unacceptable for inclusion in New and Nonofficial Remedies because it is an unscientific mixture sold with unwarranted and unestablished claims under an objectionable proprietary name.

### NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

**PROTAMINE ZINC INSULIN** (See New and Nonofficial Remedies, 1938, p. 338).

**Protamine, Zinc and Iletin (Insulin, Lilly)** (See New and Nonofficial Remedies, 1938, p. 338).

The following dosage form has been accepted:

*Protamine, Zinc & Iletin (Insulin, Lilly), 80 units, 10 cc.: Each cubic centimeter contains 80 units of insulin, together with protamine and approximately 0.16 mg. of zinc.*

**Protamine Zinc Insulin-Mulford** (See New and Nonofficial Remedies, 1938, p. 338).

The following dosage form has been accepted:

*Protamine Zinc Insulin-Mulford, 80 units, 10 cc.: Each cubic centimeter contains 80 units of insulin, together with protamine and approximately 0.16 mg. of zinc.*

**Protamine Zinc Insulin-Squibb** (See New and Nonofficial Remedies, 1938, p. 339).

The following dosage form has been accepted:

*Protamine Zinc Insulin-Squibb, 80 units, 10 cc.: Each cubic centimeter contains 80 units of insulin, together with protamine and approximately 0.16 mg. of zinc.*

**STAPHYLOCOCCUS TOXOID** (See New and Nonofficial Remedies, 1938, p. 422).

The National Drug Co., Philadelphia.

*Staphylococcus Toxoid (The National Drug Co.).—Prepared from toxin produced by selected strains of Staphylococcus aureus. The toxin, to which formaldehyde is added, is kept at 37 C. during the period necessary for the toxin to be converted into toxoid. The toxin is injected intradermally into rabbits to determine the smallest dose which will cause necrosis of the skin. After detoxification it must not produce necrosis in a dose of 0.2 cc. The toxin is tested for its hemolyzing action on rabbit cells; it must have a hemolytic test (L. H.) dose of not completely less. The detoxified toxin (toxoid) in a 1 cc. dose must not completely hemolyze a 1 per cent suspension of washed rabbit cells. Mice given intraperitoneal injections of 0.5 cc. doses of undiluted toxoid must survive four days; guinea pigs receiving 5 cc. of undiluted toxoid subcutaneously must have no local or general adverse symptoms during the period of observation (one week); rabbits receiving 3 cc. of toxoid per kilogram of*

weight, intravenously, must show no toxic symptoms within four days. Sterility tests are made by culture of toxoid in Smith fermentation tubes. The formaldehyde solution must not exceed 0.4 per cent by volume, 1 cc., 2 cc. and 3 cc. Potency tests are made in accordance with the requirements of the National Institute of Health: three doses of staphylococcus toxoid given, to rabbits intramuscularly at weekly intervals must produce at least 3 units of staphylococcus antitoxin per cubic centimeter of rabbit serum, as measured by the hemolytic method.

Staphylococcus toxoid (The National Drug Co.) is marketed in two dilutions: Dilution No. 1, 5 cc. ampul-vial containing in each cubic centimeter the equivalent of 100 minimum necrotizing doses of the original toxin; and Dilution No. 2, 5 cc. ampul-vial containing in each cubic centimeter the equivalent of 1,000 minimum necrotizing doses of the original toxin.

**CEVITAMIC ACID** (See New and Nonofficial Remedies, 1938, p. 480).

The following dosage form and brand have been accepted:

*Mead's Cevitamic Acid Tablets:* Each tablet contains 25 mg. cevitic acid equivalent to 500 international units of vitamin C.  
Prepared by Mead Johnson and Co., Evansville, Ind.

**Cebione** (See New and Nonofficial Remedies, 1938, p. 481).  
The following dosage forms have been accepted:

*Scaled Tubes Cebione, 0.5 Gm.*  
*Scaled Tubes Cebione, 1.0 Gm.*

**DIGITALIS** (See New and Nonofficial Remedies, 1938, p. 186).

*Capsules Digitalis Leaf, 0.1 Gm. (1½ grains)-Abbott:* Each capsule represents 1 U. S. P. unit.  
Prepared by Abbott Laboratories, North Chicago, Illinois.

**ANTIANTHRAX SERUM** (See New and Nonofficial Remedies, 1938, p. 394).

Jensen-Salsbery Laboratories, Inc., Kansas City, Mo.

*Antianthrax Serum.*—Prepared from cattle subjected to intradermal, followed by increasing doses of intravenous, injections of live cultures of *Bacillus anthracis*. Contains 0.5 per cent phenol as preservative. Marketed in vials containing 100 cc.  
*Dosage.*—Initial doses of from 50 to 100 cc. may be administered intravenously at three to twelve hour intervals as indicated; for subcutaneous injection, from 3 to 12 cc. into tissues about local lesions.

**EPHEDRINE HYDROCHLORIDE** (See New and Nonofficial Remedies, 1938, p. 227).

**EPHEDRINE HYDROCHLORIDE-LAKESIDE.**—A brand of ephedrine hydrochloride-U. S. P.

Manufactured by the Lakeside Laboratories, Inc., Milwaukee, Wis. No U. S. patent or trademark.  
*Solution Ephedrine Hydrochloride-Lakeside, 3%:* It is preserved with chlorbutanol, 0.5 per cent.

**EPHEDRINE SULFATE** (See New and Nonofficial Remedies, 1938, p. 228).

**EPHEDRINE SULFATE-LAKESIDE.**—A brand of ephedrine sulfate-U. S. P.

Manufactured by the Lakeside Laboratories, Inc., Milwaukee, Wis. No U. S. patent or trademark.  
*Ampoules Ephedrine Sulfate-Lakeside, 0.05 Gm. (¾ grain), 1 cc.*  
*Capsules Ephedrine Sulfate-Lakeside, 0.025 Gm. (¾ grain).*  
*Capsules Ephedrine Sulfate-Lakeside, 0.05 Gm. (¾ grain).*

**STRONG PROTEIN SILVER** (See New and Nonofficial Remedies, 1938, p. 443).

**SILVER PROTEIN STRONG-MERCK.**—A brand of strong protein silver-U. S. P.

Manufactured by Merck & Co., Rahway, N. J. No U. S. patent or trademark.

**ETHYL AMINO BENZOATE** (See New and Nonofficial Remedies, 1938, p. 80).

**BENZOCAINE-MERCK.**—A brand of ethyl aminobenzoate-U. S. P.

Manufactured by Merck & Co., Rahway, N. J. No U. S. patent or trademark.

**BISMUTH AND POTASSIUM TARTRATE** (See New and Nonofficial Remedies, 1938, p. 146).

**BISMUTH AND POTASSIUM TARTRATE-MERCK.**—A brand of bismuth and potassium tartrate-U. S. P.

Manufactured by Merck & Co., Rahway, N. J. No U. S. patent or trademark.

**CARBROMAL** (See New and Nonofficial Remedies, 1938, p. 155).

**CARBROMAL-MERCK.**—A brand of carbromal-U. S. P.

Manufactured by Merck & Co., Rahway, N. J. No U. S. patent or trademark.

## Council on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

#### LARSEN'S "FRESHLIKE" BRAND STRAINED VEGETABLE SOUP

*Manufacturer.*—The Larsen Company, Green Bay, Wis.

*Description.*—Canned, strained vegetable soup containing carrots, potatoes, barley, tomatoes, peas, green beans, celery, spinach and salt.

*Manufacture.*—Selected fresh vegetables are cleaned, trimmed, peeled, mixed with whole barley grains and salt, vacuumized, cooked to proper softness and texture, and double screened. The mixture is filled into cans, sealed under vacuum, and heat processed.

*Analysis* (submitted by manufacturer).—Moisture 85.3%, total solids 14.7%, ash 1.1%, fat (ether extract) 0.2%, protein (N × 6.25) 2.2%, crude fiber 0.5%, carbohydrates other than crude fiber (by difference) 10.7%, calcium (Ca) 0.027%, phosphorus (P) 0.157%, iron (Fe) 0.0009%.

*Calories.*—0.5 per gram; 14 per ounce.

#### CLAPP'S CHOPPED APPLE SAUCE

*Manufacturer.*—Harold H. Clapp, Incorporated, Rochester, N. Y.

*Description.*—Canned apple sauce prepared from chopped apples, sweetened with sugar.

*Manufacture.*—Baldwin apples are graded, washed to remove spray residues, again washed, peeled, cored, inspected, trimmed by hand, water sprayed and mechanically chopped. The apples are weighed and a definite amount of sugar is added. The mixture is heated in an atmosphere of steam, adjusted to standard consistency, filled into cans, sealed, processed under pressure in steam retorts and cooled.

*Analysis* (submitted by manufacturer).—Moisture 85.8%, total solids 14.2%, ash 0.4%, fat (ether extract) 0.7%, protein (N × 6.25) 0.1%, crude fiber 2.1%, carbohydrates other than crude fiber (by difference) 10.9%.

*Calories.*—0.5 per gram; 14 per ounce.

#### MRS. PALEY'S BABY FOOD—STRAINED BEEF

*Manufacturer.*—Paley-Sachs Food Company, Houston, Texas.

*Description.*—Canned sieved scraped beef, U. S. inspected and passed by the Department of Agriculture. Slightly seasoned with salt.

*Manufacture.*—Lean beef, U. S. inspected and passed by the Department of Agriculture, is scraped to remove tough sinew, and ground. Definite proportions of water and salt are added and the mixture is heated to from 71 to 77 C., strained, filled into cans, sealed and heat processed at 116 C. for one hour.

*Analysis* (submitted by manufacturer).—Moisture 82.5%, total solids 17.5%, ash 1.6%, fat (ether extract) 0.5%, protein (N × 6.25) 14.4%, carbohydrates (by difference) 1.0%.

*Calories.*—0.66 per gram; 19 per ounce.

#### CELLU BRAND TOMATO JUICE

*Distributor.*—Chicago Dietetic Supply House, Inc., Chicago.

*Description.*—Canned tomato juice; no added salt.

*Manufacture.*—Manufactured in essentially the same manner as Kemp's Sun-Ray Brand Tomato Juice (THE JOURNAL, Dec. 13, 1930, p. 1835).

*Analysis* (submitted by manufacturer).—Moisture 94.4%, total solids 5.6%, ash 0.4%, fat (ether extract) 0.3%, protein (N × 6.25) 1.0%, reducing sugar as invert 3.6%, sucrose (by copper reduction) 0.1%, crude fiber 0.2%, carbohydrates other than crude fiber (by difference) 3.7%.

*Calories.*—0.22 per gram; 6 per ounce.

SATURDAY, NOVEMBER 26, 1938

## ASPHYXIA OF THE NEWBORN

According to the statistics of the birth registration area about 80,000 infants die annually at birth in this country; 30,000 more die on the first day from causes which, almost without exception, are of natal origin. For every hundred babies born alive there are five, or one in twenty, that die within the first twenty-four hours of extra-uterine life. As Yandell Henderson pointed out, the first quarter of an hour after birth is the most dangerous period of life. Its mortality is as great as that of any subsequent month. The principal causes of infant mortality during the first twenty-four hours are prematurity, cerebral hemorrhage and asphyxia. These factors are so interrelated that it is impossible to establish precisely their relative importance. Intra-uterine pneumonia due to aspiration of amniotic fluid, plus a bacterial factor, are responsible for a certain number of deaths and, rarely, drugs administered to the mother.

Apnea of the newborn naturally demands consideration of the mechanism which initiates the respiration shortly after the fetus is born and the cord is clamped. The mechanical theory of Preyer that the reflex stimulation of the trauma of labor acts as a stimulant to the respiratory center is contradicted by everyday clinical observations. Rough palpation, attempts at manual version or application of forceps do not initiate breathing as long as the fetus remains in utero with the placental circulation intact. The mechanical theory led to the establishment of the time honored and not infrequently vicious methods of resuscitation, such as slapping, swinging or plunging the infant into an ice cold bath. Ahlfeld delivered several women in a warm saline bath and found that respiration began as usual, thus refuting the view that skin irritation as the result of exposure to air and change of temperature causes the infant to breathe. The chemical theories advanced in explanation of the initiation of the first gasp after the cord is clamped were (1) insufficient oxygen, (2) excess of carbon dioxide and (3) increased blood

pressure in the brain. Barcroft<sup>1</sup> administered a carbon dioxide mixture to the mother and noted that it had no effect whatever on the infant. Eastman<sup>2</sup> studied the carbon dioxide tension of the blood in infants at birth and found that respiration began whether the tension of this gas was high or low and seemed to bear no relationship to the carbon dioxide tension. Barcroft established in the goat that lack of oxygen is the cause of the onset of respiration. According to Eastman's investigations, however, the oxygen content of the blood at birth showed no relationship between the concentration of this gas and respiration except possibly that infants with a high content of oxygen in the blood breathe more readily and that those with an extremely low content are apneic.

An entirely different approach to the problem was made possible by the unique investigations of Snyder and Rosenfeld.<sup>3</sup> They have established the existence of rhythmic respiratory movements of the fetus in utero long before term. Their method consisted of sectioning the spinal cord of the maternal animal at the level of the second lumbar vertebra, under local anesthesia, in order to permit laparotomy without the use of a general anesthetic. Incision of the abdomen at the lower midline was carried out beneath the surface of a bath of Ringer solution at 37 C. The gravid uterus readily escaped from the peritoneal cavity and came under direct observation. Gases and volatile anesthetics were administered through a T shaped cannula introduced by tracheotomy under local anesthesia. The authors have observed the occurrence of regular respiratory movements under these experimental conditions in full term fetuses. They have thus established that the fetal respiration is not initiated at birth and that the fetuses of the rabbit, cat and guinea pig show rhythmic respiratory movements within the uterus, instead of a state of prolonged apnea. They have further established that the regularity of fetal respiration depends on the oxygen and the carbon dioxide level of fetal blood, that the oxygen want depresses or abolishes fetal respiratory movements and that a carbon dioxide deficit results in depression or apnea of the fetus, showing that a certain level of carbon dioxide is essential for the maintenance of fetal respiration.

Snyder and Rosenfeld also made observations of the fetal movements transmitted through the abdominal wall in a series of women near term.<sup>4</sup> They recognized unmistakable, spontaneous fetal movements which continued at the regular rhythm for many minutes. These movements were recorded with the aid of motion pictures. They have thus given both experimental and

3. Snyder, F. F., and Rosenfeld, Morris: Direct Observation of Intra-Uterine Respiratory Movements of the Fetus and the Role of CO<sub>2</sub> and Oxygen in Their Regulation, *Am. J. Physiol.* 119:153 (May) 1937.

4. Snyder, F. F., and Rosenfeld, Morris: Intra-Uterine Respiratory Movements of the Human Fetus, *J. A. M. A.* 108:1946 (June 5) 1937.

clinical confirmation of the intra-uterine respiratory activity first advanced by Schultze, Ahlfeld, Weber and Reifferscheid. In view of these facts the respiratory failure of the newborn must be regarded, according to Snyder and Rosenfeld, as an expression of a previous activity suppressed rather than failure of some new mechanism to begin functioning at birth.

The keynote to the treatment of asphyxia neonatorum, as emphasized by Eastman in his illuminating review, is gentleness. The removal of fluid and mucus from the air passages is the first step and in most instances the only one required. This may be accomplished by posture, by gentle wiping of the mouth and pharynx with the little finger covered by gauze, and by the use of suction with a catheter. The simplest, as well as the oldest, method of mouth to mouth insufflation has its obvious practical advantages as well as definite limitations and objections, the principle of which is that rupture of the pulmonary alveoli may occur unless the method is practiced gently.

Yandell Henderson warns obstetricians to be more conservative in administering narcotics shortly before delivery,<sup>5</sup> in view of the ample evidence that such drugs act far more on the baby than on the mother. He further emphasizes that the passage of a soft catheter into the trachea of an apneic baby is so simple an operation and insufflation by the Meltzer-Flagg technic is so effective that there is little justification for any other procedure. The technic for artificial respiration of the newborn presented by Flagg<sup>6</sup> insists on adherence to surgical principles, namely exposure of the field with the aid of a small laryngoscope, removal of foreign material under direct vision and, when necessary, endotracheal intubation and insufflation of oxygen and carbon dioxide under controlled pressure.

### PROTRACTED MODERATE SCURVY

Szent-Györgyi,<sup>1</sup> who has contributed much of our accurate knowledge of the nature of vitamin C and the body's requirements for this substance, has reiterated his opinion that the quantity of vitamin C which protects the organism against scurvy may not be sufficient for optimal health and growth, because scurvy is not the first sign of vitamin C deficiency but rather a late, if not actually premortal, symptom. Man, it is said, lives under conditions in our present civilization which subject him frequently to partial vitamin deficiency. Such deficiencies may fail to produce definite characteristic symptoms but if continued for a sufficient time will bring about pathologic changes. The clinical symptoms which result from protracted or intermittent suboptimal intake of vitamin C have been too indefinite

to constitute acceptable criteria for establishing the diagnosis of chronic vitamin C deficiency.

Accurate visualization of the pathologic changes in the bones and cartilage which may result from a protracted mild deficiency of vitamin C for children and for adults has been accomplished by Park, Guild, Jackson and Bond,<sup>2</sup> by Wolbach and Howe<sup>3</sup> and more recently by Ham and Elliott.<sup>4</sup> Various workers have expressed differences of opinion or of interpretation of the pathologic changes. Park and his associates included a thorough analysis of the roentgenologic appearance as well as microscopic changes in the scorbutic bones of children. They believe that bones continue to grow in length in scurvy because the cartilaginous epiphysal plate continues to grow. They think, however, that the cartilage is piled up unossified on the diaphysal side of the plate as a honeycomb of heavily calcified cartilage which shows readily in the roentgenograms.

Ham and Elliott used guinea pigs of both sexes fed on a diet which contained less than the basic requirement of vitamin C but a sufficient amount of this vitamin to prevent the development of the more commonly recognized results of acute scurvy. The control animals received, in addition to the basal diet, 1 cc. of orange juice per hundred grams of body weight, plus an additional 1 cc. as a margin of safety, in accordance with the recommendation of Dann and Cowgill.<sup>5</sup> Observations were made on five groups of animals: controls, those receiving no vitamin C, and three groups, each of which were subjected to a different degree of deficiency. Since the diaphysal lesions of severe scurvy had already been carefully studied in both man and the experimental animals by several investigators, the results in this group were not included. In the experimental animals the epiphysal plate was thinner than in the normal animals and there was not the accumulation of cartilage on the diaphysal side of the plate which had been described by Park and his associates and which, in all probability, represented a much more acute phase of this deficiency disease.

In protracted moderate scurvy, which probably approximates that most commonly seen in human beings, the experimental animals showed microscopic changes both in the diaphyses and in the epiphyses. The cancellous scaffolding of bony trabeculae in the juxta-epiphysal region of the diaphysis was poorly formed. The number and activity of the cells concerned in building this bony scaffolding was diminished. Although growth of the bones continued, they became exceedingly weak and fractures were commonly found

on the diaphysial side of the epiphysial plate. The epiphysial cartilage plate was thinner than in the control animals at the point where it caps the marrow cavity, and the columns of cartilage cells were less regular. The microscopic examination of the epiphyses revealed an uncalcified zone in the region nearest the articular cartilage and a calcified zone in the layer of bone which underlies and supports the articular cartilage. The supporting bone was diminished in amount and in some places there was none to support the articular cartilage itself. Ham and Elliott are convinced that in growing scorbutic bones the portion of the shaft laid down before the onset of the disease was affected much less than the tissue laid down afterward. This would indicate that scurvy inhibits the formation of new bone more than it speeds up bone absorption.

The "jellation theory" was advanced by Aschoff and Koch,<sup>6</sup> who observed that zones of active normal bone formation were replaced in scurvy by a marrow framework which contained little firm intercellular substance. In 1926 Wolbach and Howe studied the bones of scurvy and stated that they believed the loose texture described by Aschoff and Koch was caused by the presence of liquid intercellular substance. This liquid intercellular substance, according to this theory, simply failed to jell because it lacked the cement material. Ham and Elliott did not agree but reported that they found no evidence of the accumulation of a jelling fluid intercellular substance. On the contrary, there seemed to be a general depression of all the activity usually concerned in bone formation.

#### BONE MARROW IN APLASTIC ANEMIA

The exact nature of the cellular changes in the bone marrow in aplastic anemia has received little attention despite the fact that numerous clinical studies have been made on patients with this disease. Some evidence,<sup>1</sup> however, suggests that the abnormality is not necessarily a lack of immature forms of erythrocytes in the bone marrow, as hyperplasia of the marrow rather than aplasia is frequently found. It might be concluded, therefore, that in this type of anemia there is a failure of the normal process of maturation of the red cell. However, the fact should be emphasized that the abnormality in maturation of erythrocytes which occurs in aplastic anemia must differ from that in pernicious anemia, as liver therapy does not favorably affect the former.

The suggestion that there is an impairment in the maturation of erythrocytes in aplastic anemia has recently been investigated further<sup>2</sup> on patients with

this disease. Differential counts were made on biopsy specimens of sternal marrow stained both supravitaly and in the ordinary way. The pathologic changes in the cellular composition of the marrow permitted classification into five distinct groups. In one the characteristic feature was a replacement of hemopoietic tissue by a cellular structure composed of megakaryocytes in various stages of development, a true "myelophthisic anemia." In the second group the marrow was sclerotic and, in the remaining three groups, differences only in the cellularity of the marrow were evident. In the latter three the marrows were either aplastic, active or hyperplastic; in each, however, the fundamental abnormality was a failure of maturation of the hemopoietic cells at an early undifferentiated stage. This observation thus supports the view that a primary etiologic factor in aplastic anemia is an impairment in the normal process of erythrocyte maturation.

Another observation of particular interest was the similarity between the appearance of the marrow from patients with aplastic anemia and that from patients with acute agranulocytosis. A similar failure in the process of cell maturation was observed. The authors therefore suggest that "aplastic anemia and acute agranulocytosis may have some etiologic factor in common." In practical support of this view, it is pointed out that anemia frequently supervenes in cases of chronic agranulocytosis, in which early death or spontaneous remissions do not occur and thus mask the more slowly developing disturbances in erythropoiesis. This significant suggestion merits continued careful investigation.

#### Current Comment

##### TYPHOID MARY DIES

The death on November 11 of Mary Mallon, aged 70, who achieved notoriety as the first typhoid carrier recognized in the United States, brings to a close a strange history. "Typhoid Mary" was a cook whose employment was almost invariably accompanied by an outbreak of typhoid. Her role in the spread of this disease was finally recognized in 1907 and she was forcibly kept out of circulation at the Detention Hospital of the Health Department for three years. Following her voluntary release in 1910 she disappeared for five more years and, although her history neither before her first detention nor after her disappearance could be learned completely, she was known to have caused at least ten outbreaks of typhoid with fifty-one cases. From 1915 until her recent demise she was held by the New York City Department of Health in the Riverside Hospital on North Brother Island. She became reasonably adapted to her changed status, and her stools were constantly used by the health department as a control for mediums used in the culture of typhoid bacilli. "Typhoid Mary" will be known forever in association with the typhoid carrier problem.<sup>1</sup>

### JUDGE LIMITS SCOPE OF GRAND JURY INVESTIGATION

District Court Justice Proctor on November 17 quashed two thirds of a subpoena which had ordered the American Medical Association to produce to the grand jury a wide variety of certain records, some going back as far as twenty-two years. In ordering the first two paragraphs of the subpoena quashed, Judge Proctor struck out that part which ordered the American Medical Association to produce certain records dealing with the following organizations: Illinois Social Hygiene League; Public Health Institute; United Medical Service; Civic Medical Center and Dr. Louis E. Schmidt, all of Chicago; Milwaukee Medical Center, Milwaukee; Trinity Hospital, Little Rock, Ark.; Ross-Loos Medical Group, Los Angeles, and Community Hospital, Elk City, Okla. The original subpoena had ordered a sweeping probe of all records concerning these organizations. In his opinion, Justice Proctor is reported to have said:

The assertions made in the motion and in arguments that compliance with the subpoena will require an examination for the stated period of every paper in all the files of the Association scattered through its separate departments, occupying a large nine-story building in Chicago, have not been challenged in any way. The statement seems to be fair when one visualizes the situation in the light of the sweeping terms of the subpoena. To fully and strictly comply therewith every paper of whatever nature containing the slightest reference to the ten named organizations and persons for the periods specified must be found and produced. In most cases the dates go back to 1930; in one case to 1916. In addition it would be necessary to find over a period of about four years all papers of every kind containing any possible reference to persons or bodies engaged in providing, proposing or attempting to provide prepaid medical care or low-cost group medical practice. The marks for identifying these papers are not prescribed subjects that might have some possible relevancy to the nature of the grand jury's investigation. The only means for finding them is to examine all papers for some reference, however casual or unimportant, to specify classes of persons, apparently large, who may in any way have been engaged in any movement to promote prepaid or low-cost group medical service. Moreover, it is presupposed that the Association knows the names of all those so engaged. Doubtless many are known, but it seems likely they would be met with great difficulty and uncertainty in attempting to identify all. In a few of these considerations, I cannot but regard the provisions of the first and second paragraphs of the subpoena as imposing an unreasonable and oppressive burden.

The third paragraph of the subpoena, which Justice Proctor allowed to stand, orders the American Medical Association to produce all correspondence, memoranda or other documents, dating from Jan. 1, 1932, relating to:

The Justice Department's investigations of relations of the American Medical Association and the District Medical Society with the Group Health Association Inc. of Washington, D. C.

Any requirement or proposal of the American Medical Association that hospital staff members belong to local branches of the American Medical Association.

Instances where approval of hospitals for intern training by the American Medical Association were revoked because of the membership of the staffs of such hospitals.

In his opinion, as noted, Justice Proctor considered the demand of the records indicated in the first two sections of the subpoena as "an unreasonable and oppressive burden."

### HEARINGS BEFORE THE GRAND JURY IN WASHINGTON

The following four witnesses from the Episcopal Eye, Ear and Throat Hospital, Washington, D. C., are reported to have appeared last week before the Special Grand Jury in Washington, D. C.: Henry P. Blair, chairman of the executive committee; Miss Anita Richardson, staff secretary; Dr. Carl Henning, secretary of the board of directors, and Dr. Maurice A. Selinger, secretary of the medical board. Dr. Thomas E. Mattingly, Washington, D. C., also testified before the grand jury.

### RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company, entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-

six weeks. The program is broadcast over the Blue network of the National Broadcasting Company each Wednesday at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).<sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

November 30. Rest, Relaxation and Recreation.  
December 7. Tuberculosis and the Teens.  
December 14. What Shall We Eat?

### EXHIBIT SYMPOSIUM ON HEART DISEASE

An exhibit symposium on heart disease has been arranged for the Scientific Exhibit at the St. Louis session of the American Medical Association, May 15-19, 1939. The symposium will be presented with the cooperation of the American Heart Association, under the auspices of a committee of which Dr. Thomas M. McMillan, 2044 Locust Street, Philadelphia, is chairman. Application blanks for space in the exhibit may be obtained from Dr. McMillan or from the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ADDITIONAL MEDICAL COLLEGE NEWS AND ARTICLES APPEAR IN THE STUDENT SECTION, PAGE 2059.

### ARKANSAS

**Changes in Health Officers.**—Dr. Ulys Jackson, Harrison, has been appointed medical director of district 14 of the state department of health, with headquarters in Marshall.—Dr. Earnest L. Thompson, Hot Springs National Park, has been appointed in charge of the Gariand County health department, succeeding the late Dr. James F. Merritt.

**Society News.**—The White County Medical Society was addressed September 14 in Searcy by Drs. Doyle W. Fulmer on "Malaria in Arkansas"; Barnett P. Briggs, "Respiratory Infections in Children," and Merlin J. Kilbury, "Changes in the Cervix and Uterus." All are of Little Rock.—At a meeting of the Ouachita County Medical Society in Camden September 1 the speakers were Drs. Raymond C. Cook and Kingsley W. Cosgrove, both of Little Rock, on "External Diseases of the Eye of Interest to the General Practitioner" and "The Ophthalmoscope and the General Practitioner" respectively.—Dr. Frederick H. Krock, Fort Smith, discussed "Factors in Estimation of Disability" before the Sebastian County Medical Society September 13.

### CALIFORNIA

**Course on Fractures.**—The University of California Medical School, San Francisco, will offer a course on "Treatment of Fractures" at the San Francisco Hospital December 14-16. The course, which will be short and comprehensive, has been designed to meet the needs of physicians engaged in private practice. Additional information may be obtained from the dean's office at the university, Medical Center, San Francisco.

**Society News.**—Dr. Lodewyk Bendikson, Los Angeles, discussed "The Technical and Scientific Program of a Modern Research Library" before the Hollywood Academy of Medicine November 10.—The San Francisco County Medical Society devoted its meeting November 8 to a symposium on pneumonia

1. Owing to program conflicts, there will be no Chicago broadcast of the network program. Instead, a recording of the program will be broadcast over station WENR at 8 p. m. each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

with the following speakers: Drs. Herbert C. Moffitt, Jacob C. Geiger, John W. Brown and Edwin L. Bruck, Miss Cordula Kohl and Miss N. M. Anderson, R.N.

### CONNECTICUT

**Parrots Barred from Connecticut.**—The importation of parrots into Connecticut is prohibited under a recent revision of the state sanitary code. The regulation also prohibits the purchase, breeding, sale or giving away of any birds belonging to the psittacine family but provides that the importation or breeding of such birds for scientific research or exhibition in public zoological gardens may be permitted subject to the approval of the state department of health.

**The Terry Lectures.**—Dr. Henry E. Sigerist, director of the Institute of the History of Medicine, Johns Hopkins University School of Medicine, Baltimore, delivered the Dwight Harrington Terry Foundation lectures at Yale University School of Medicine, New Haven, November 2-5. The main topic of discussion was "Medicine and Human Welfare"; individual titles of the lectures were "The Significance of Disease," "The Significance of Health" and "The Physician's Mission." The lectures are named after the late Dwight H. Terry, Plymouth, who gave \$100,000 to establish the lectureship.

### GEORGIA

**The Jonte Equen Memorial Lecture.**—Dr. Wells P. Eagleton, Newark, N. J., delivered the second Jonte Equen Memorial Lecture before the Fulton County Medical Society, Atlanta, October 21. His subject was "Allergic and Toxic Types of Curable Bacterial Meningitis." The lectureship was established a year ago by Dr. Murdock Equen in memory of his father.

**District Meeting.**—The Second District Medical Society was addressed in Bainbridge October 14, among others, by Drs. John W. Mobley Jr., Pelham, on "Hookworm—Its Economic and Medical Importance in Southwest Georgia"; Thomas C. Davison, Atlanta, "Thyroids," and Walter P. Rhyne, Albany, "Relationship of Nasal Infection and Sinusitis with Infection of the Middle Ear."

**Society News.**—Dr. Grayson L. Carroll, St. Louis, addressed the Georgia Urological Association in Atlanta October 13 on "The Trend Toward Conservatism in Urological Treatment."—The Fulton County Medical Society was addressed October 20 by Drs. Benjamin Russell Burke and William B. Armstrong on "The Normal and Pathologic Larynx" and by Drs. Earle H. Floyd and James L. Pittman on "The Recuperative Powers of the Kidney."

### ILLINOIS

**Conference of Health Officers and Public Health Nurses.**—The annual conference of Illinois Health Officers and Public Health Nurses will be held in the auditorium of the Centennial Building, Springfield, November 30-December 1, with Dr. Albert C. Baxter, acting state health director, as chairman. Out of state speakers will include:

- Dr. Wilson G. Smillie, New York, The Development of Public Health in the United States.
- Dr. Harry S. Mustard, New York, Rural Health Problems.
- Dr. Bruce Douglas, Detroit, Newer Aspects of the Tuberculosis Problem.
- Dr. Adolph S. Rumreich, U. S. Public Health Service, Washington, D. C., Administrative Control of Pneumonia.
- Dr. Nels A. Nelson, Boston, Administrative Control of Syphilis and Gonorrhea.
- Dr. Gaylord W. Anderson, Minneapolis, Scarlet Fever Control.
- Dr. Arthur T. McCormack, Louisville, Ky., Outlook in Public Health.
- Dr. Franklin G. Ebaugh, Denver, Mental Hygiene in Public Health.
- Sophie Nelson, R.N., Boston, Organizing Community Nursing Service.
- John C. Brauer, D.D.S., Des Moines, Dental Hygiene in Public Health.

### Chicago

**Annual Institute Meeting.**—Dr. Joseph A. Capps will deliver the presidential address at the twenty-third annual meeting and dinner of the Institute of Medicine of Chicago December 6; his subject will be "Prognosis of Subacute Bacterial Endocarditis."

### INDIANA

**Changes in Health Officers.**—Dr. William D. Hart has been appointed director of district health unit 4, Rising Sun, succeeding Dr. George M. Brother, who is taking a year's study at Johns Hopkins University School of Hygiene and Public Health, Baltimore. Dr. Lewis C. Robbins is acting chief of the bureau of local health administration, state board of health, Indianapolis, while Dr. John W. Ferree, chief of the bureau, completes a course at the school of hygiene and public

health.—Dr. John S. Woolery, Bedford, has been appointed health officer of Lawrence County, filling the unexpired term of the late Dr. Wesley H. McKnight.

**Society News.**—The Fayette-Franklin County Medical Society was addressed in Connersville October 11 by Dr. Don E. Kelly, Indianapolis, on "Treatment of Common Skin Diseases."—The Parke-Vermillion County Medical Society heard Dr. Caryle B. Bohner, Indianapolis, discuss "Diagnosis and Treatment of Allergic Diseases" October 19.—Dr. Florian E. Schmidt, Chicago, addressed the Montgomery County Medical Society in Crawfordsville October 20 on "Serum Treatment of Pneumonia."—At a meeting of the St. Joseph County Medical Society in South Bend October 18 the speakers were Drs. Fred P. Eastman and Edward L. Rigley, South Bend, on "History of Early Medicine in St. Joseph County" and "Intrinsic Lesions of the Esophagus."—Dr. John E. Dalton, Indianapolis, discussed "Syphilis and the Pregnant Woman" before the Randolph County Medical Society in Winchester October 10.—The Floyd County Medical Society was addressed in New Albany October 14 by Dr. James W. Baxter Jr., New Albany, on "Sulfanilamide and Estrogenic Substance."

### KANSAS

**Health Talks for School Children.**—The speakers' bureau of the Sedgwick County Medical Society began a series of lectures October 27 to continue for sixteen weeks designed for school boys on topics of general health interest. The list of subjects coincides with the topics to be broadcast for a given week on the American Medical Association's radio program "Your Health." The talks are twenty minutes in length followed by twenty minutes of discussion and will be given in the auditorium of the North and East high schools, Wichita, Mondays and Thursdays respectively.

**Society News.**—Dr. Fred J. McEwen, Wichita, addressed the Mitchell County Medical Society at Beloit October 12 on the electrocardiograph.—At a meeting of the Wichita League for the Hard of Hearing October 12 Drs. Lloyd Gilbert Little spoke on "The Psychiatric Aspect of the Hard of Hearing" and Ernest E. Tippin, "Conservation of Hearing."—The Johnson County Medical Society was addressed in Olathe October 10 by Drs. Wayne C. Bartlett and James S. Hilbard Jr. on "Surgical Gallbladder" and "Surgical Treatment of Ulcerous Lesions of the Stomach" respectively.—At a meeting of the Pratt County Medical Society October 28 Drs. Christian A. Hellwig spoke on "Uterine Bleeding After the Age of Forty" and Howard C. Clark, "Prenatal Care." Both are from Wichita.—The Wyandotte County Medical Society was addressed October 18 by Drs. Ingall H. Neas, Kansas City, on "Pneumothorax Therapy" and Leland F. Glaser, Kansas City, "Clinical Results Obtained by Artificial Fever Therapy."

### MICHIGAN

**New Unit at State Hospital.**—Construction has started on the second unit of the \$1,039,196 state hospital building program in Pontiac to provide accommodations for 700 additional patients. The new building will be located between the present administration building and the neuropsychiatric hospital, now under construction, and will house a general hospital unit. The neuropsychiatric unit will cost \$698,547. Financed partially by PWA funds, the building program at Pontiac is part of the \$11,000,000 state hospital building project.

**Guest Speakers in Wayne County.**—Dr. Daniel C. Darrow, associate professor of pediatrics, Yale University School of Medicine, New Haven, Conn., addressed a joint meeting of the Wayne County Medical Society and the Detroit Physiological Society in Detroit November 7 on "Salt Deficit—The Essential Feature of Clinical Dehydration." Dr. Martin E. Rehfuess, Philadelphia, addressed the medical section of the county medical society November 14 on "Gallbladder Infections" and Dr. Olga S. Hansen, Minneapolis, will speak before the surgical section November 28 on "Cardiac Problems in Pregnancy."—Dr. Eric M. Matsner, New York, gave an illustrated lecture November 1 before the Detroit Obstetrical and Gynecological Society; his subject was "Trends in Contraceptive Practice."

### MINNESOTA

**Protest Appointment of Physicians for City Employees.**—Over the protest of the Ramsey County Medical Society and the union of city and county employees, the city council of St. Paul appointed five physicians and surgeons to care for all city employees injured in line of duty. The medical society and the union contended that the plan infringed the right of

employees to choose their own physicians. Following the appointments the Ramsey County society adopted a resolution urging members to decline such appointments. In addition, the St. Paul Trades and Labor Assembly disapproved the plan and demanded that the Labor members of the council ask for a reconsideration. The medical society in its resolution pointed out that the state supreme court has held that an employee should have the unquestioned right to choose his medical attendant. In the same opinion it was held that the fact that the employer is a municipality and employs a physician cannot alter the construction of the statute. It was reported that three of the physicians appointed had refused to serve.

### MISSOURI

**District Meeting.**—The Eighth Councilor Medical Society was addressed in Joplin October 20 by Drs. James G. Carr, Chicago, on the syphilitic heart and Francis T. H'Doubler, Springfield, report of the International Goiter Conference in 1938. A symposium on treatment of accidental injuries was presented by Drs. Charles T. Reid, Joplin, on "The Eye and Highway Accidents"; Frank D. Dickson, Kansas City, "Roadside Emergency Care and Highlights on the First Dressing," and Donald F. Coburn, Kansas City, head injuries.

### MONTANA

**Personal.**—Dr. Leo F. Hall, formerly of Berea, Ohio, has been appointed health officer for Helena, and Lewis and Clark counties.

**Society News.**—Dr. Enoch M. Porter, Great Falls, has been elected president of the Montana Public Health Association and Dr. William F. Cogswell, Helena, reelected secretary for the twenty-fifth successive year, according to the *Journal-Lancet*.

### NEW YORK

**Society News.**—Dr. David M. Davis, Philadelphia, addressed the Rochester Academy of Medicine November 3 on "Prevention and Treatment of Serious Infections of the Kidney."—Drs. Rufus B. Crain and Morris E. Missal addressed the Rochester Pathological Society November 17 on "The Employee with Heart Disease—His Management in Industry."

**Farmer Convicted for Storing Marihuana.**—A farmer in Columbia County was fined \$400 and received a sentence to six months' imprisonment or, in lieu of the fine, another six months' imprisonment, for harvesting and storing marihuana. Bundles of the weed valued at \$1,500 were found in an attic. The case was settled by county and local police authorities under a special provision of the criminal code providing jurisdiction over misdemeanors applying to narcotic drugs.

**Graduate Courses in Syracuse.**—The medical education committee of the Onondaga County Medical Society is sponsoring the following graduate courses of several sessions each:

Diagnosis of Common Eye Diseases, Dr. Searle B. Marlow.  
Diagnosis and Treatment of the Commoner Types of Skin Diseases, Dr. Leon H. Griggs.  
Signs and Symptoms of Gastro-Intestinal Disorders, Dr. I. Harris Levy.  
Psychiatry in General Practice and the Specialties, Dr. Noble R. Chambers.  
Minor Surgery in General Practice, Dr. Edgar M. Neptune.  
Examination of the Central Nervous System, Dr. Wardner D. Ayer.  
Gynecologic Examinations in General Practice, Dr. Nathan P. Sears.

### New York City

**Typhoid Mary Is Dead.**—Mary Mallon, for many years known as "Typhoid Mary" because she was the first typhoid carrier identified in the United States and blamed for many cases before she was forced to live in isolation, died November 11 at Riverside Hospital. "Typhoid Mary" came to the attention of health authorities in 1904, when an epidemic of typhoid spread through Oyster Bay and adjacent towns. The disease was traced to a household where Mary had been a cook. She disappeared and was not discovered until 1907, when she was again found to be cooking in a Park Avenue home. After being proven to be a carrier she was committed to the hospital on North Brother Island to live. After three years the health department released her on her promise not to accept work in which food handling was involved. Four years later an epidemic occurred in a New Jersey sanatorium; Mary had been a cook there. Shortly afterward there was an outbreak at the Sloane Maternity Hospital with two deaths. She was sent then to the island permanently. She was about 70 years of age at her death.

**Science Writers Receive Award.**—The Clement Cleveland Medal of the New York City Cancer Committee was awarded at the annual dinner November 1 to the National Association of Science Writers "for outstanding work in the campaign to control cancer." Mr. William L. Laurence, science writer for the New York *Times*, received the medal for the association. The presentation was made by Mrs. Robert G. Mead, daughter of Dr. Cleveland, for whom the medal is named. Mrs. Mead is chairman of the cancer committee's finance committee. This was the second award of the medal, the first having gone to Henry R. Luce, publisher of *Time*, Inc., for the March of Time film on cancer. Dr. John C. A. Gerster, chairman of the cancer committee, presided at the dinner and presented to Mrs. Mead a book containing personal greetings from 225 friends and associates in recognition of her twenty-five years in cancer work. Dr. Francis Carter Wood presented a preview of the cancer exhibit which is to be shown at the New York world's fair in 1939. The exhibit will be on view at the Museum of Science and Industry until January.

**Society News.**—At a meeting of the New York Roentgen Society October 17 the speakers were Drs. Maurice N. Richter on "Experimental and Pathologic Aspects of Leukemia, Lymphosarcoma and Hodgkin's Disease"; Arthur P. Stout, "Indication for Surgery"; Albert Kean and Nathan Rosenthal, "Roentgenotherapy in Leukemia," and Maurice Lenz, "Roentgenotherapy of Lymphosarcoma and Hodgkin's Disease."

—At a meeting of the Medical Society of the County of Kings October 18 the speakers were Drs. Nathan B. Van Etten on "The Doctor Sits at the Crossroads"; Robert B. Osgood, Boston, "An Interpretation of the Principles and Proposals of the Informal Committee of Physicians (The Committee of 430)," and Irvin Abell, Louisville, Ky., President of the American Medical Association, "The Attitude of the American Medical Association Toward the Proposals of the National Health Conference."—Drs. James Alexander Miller and Adrian V. S. Lambert addressed the Brooklyn Thoracic Society October 21 on "Pathogenesis and Management of Pulmonary Tuberculosis" and "Surgical Treatment of Pulmonary Tuberculosis" respectively.—Dr. Harold E. B. Pardee addressed the Medical Society of the County of Queens October 21 on "Heart Disease and Pregnancy."

### OHIO

**New Health Commissioner in Cincinnati.**—Dr. Carl A. Wilzbach, executive secretary of the Cincinnati Social Hygiene Society, was appointed health commissioner of Cincinnati November 4 to take office not later than December 1. The city has not had an official commissioner since the death of Dr. William H. Peters in 1936, according to newspaper accounts. Dr. Owen C. Fisk was made acting commissioner after the death of Dr. Peters and later resigned because of ill health. Dr. Frank K. Harder succeeded Dr. Fisk as acting commissioner and will now become assistant commissioner. Dr. Wilzbach graduated from the University of Cincinnati College of Medicine in 1922.

**Advisory Council for Research Foundation.**—Announcement is made of the appointment of a scientific advisory council for the Children's Hospital Research Foundation, Cincinnati. The council consists of Drs. Oswald T. Avery of the Rockefeller Institute for Medical Research, New York; Ernest W. Goodpasture, professor of pathology, Vanderbilt University School of Medicine, Nashville, Tenn.; Albert Baird Hastings, Ph.D., professor of biological chemistry, Harvard University Medical School, Boston, and Alfred N. Richards, Ph.D., professor of pharmacology, University of Pennsylvania School of Medicine, Philadelphia. The Children's Hospital Research Foundation was established in 1929 with funds given by Mr. William Cooper Procter. The hospital and the foundation are affiliated with the University of Cincinnati College of Medicine, Dr. Albert Graeme Mitchell, professor of pediatrics, being director of the medical service at the hospital and of the foundation. Glenn E. Cullen, Ph.D., is director of laboratories. About 150 publications have appeared from the foundation staff.

**Society News.**—The industrial and orthopedic section of the Cleveland Academy of Medicine, the Bunts Institute and the Cleveland fracture committee of the American College of Surgeons sponsored a special meeting on fractures November 16. A clinic was held in the afternoon at St. Luke's Hospital, and Dr. John Albert Key, St. Louis, delivered the Bunts Lecture at the Cleveland Clinic in the evening on "Cervical and Trochanteric Fractures of the Femur."—Dr. Clyde E. Shinkle, Cincinnati, among others, addressed the Adams County Medical Society, Winchester, October 19 on infantile paralysis.—Dr. Parke G. Smith, Cincinnati, addressed the Clinton

County Medical Society, Wilmington, October 4 on "The Importance of Abnormal Renal Mobility."—Drs. Robert F. Thaw, Akron, and William M. Skipp, Youngstown, addressed the Portage County Medical Society, Atwater, October 6 on "Treatment of Diseases of the Ear, Nose and Throat" and "Problems Confronting the Medical Profession" respectively. —Bradley M. Patten, Ph.D., Ann Arbor, Mich., addressed the Mahoning County Medical Society, Youngstown, October 18 on "The First Heart Beats and the Beginning of the Circulation Studied Microcinematographically in Living Embryos." —Dr. Wiley D. Hickey, Leipsic, was elected president of the Northwestern Ohio Medical Association at its annual meeting in Defiance in October. Dr. Daniel B. Spittler, Hoytville, was made vice president and Dr. Frederic G. Maurer, Lima, secretary.

### PENNSYLVANIA

**Society News.**—Drs. William D. Stroud and Hugh Montgomery, Philadelphia, addressed the Northampton County Medical Society at the Country Club of Northampton County October 20 on "A Seven Years Study of the Clinical Efficacy of Various Digitalis Preparations" and "Treatment of Peripheral Vascular Disease" respectively. —Drs. John P. Griffith, Pittsburgh, and Walter M. Bortz, Greensburg, addressed the Westmoreland County Medical Society, Greensburg, October 18 on "Intestinal Obstruction" and "Hypertension" respectively. —Dr. William W. Bolton, Upper Darby, addressed the Medical Society of Lycoming County October 14 on "Syphilis Program of the Pennsylvania Department of Health." —Dr. Charles F. Geschickter, Baltimore, addressed the Cambria County Medical Society, Johnstown, October 7, on "Mammary Tumors."

### Philadelphia

**Personal.**—Florence B. Seibert, Ph.D., of the Henry Phipps Institute, University of Pennsylvania, received the honorary degree of doctor of laws from Goucher College, Baltimore, October 14, when the college celebrated its fiftieth anniversary.

**Ex-Residents' Annual Dinner.**—The fifty-second annual dinner of the Association of Ex-Resident Physicians of the Philadelphia General Hospital will be held December 6 at the Bellevue-Stratford. Dr. Randle C. Rosenberger, professor of preventive medicine and bacteriology, Jefferson Medical College, will be the guest of honor. Dr. Rosenberger was assistant pathologist at the Philadelphia General Hospital in 1898, when it was known as Blockley Hospital, and was director of the laboratory from 1903 to 1919. Dr. John J. Dailey, McAdoo, Pa., president of the association, will preside at the dinner. Ex-residents who do not receive notices of the dinner are requested to send their correct addresses to the secretary, Dr. George Wilson, 133 South Thirty-Sixth Street, Philadelphia.

**Society News.**—Drs. Norman R. Ingraham and John A. Kolmer addressed the Obstetrical Society of Philadelphia November 3 on "Treatment Reactions Among Syphilitic Pregnant Women with a Report of Seven Maternal Deaths from Syphilis Therapy" and "Syphilis in Relation to Gynecology and Obstetrics with Special Reference to Diagnosis and Treatment" respectively. —Dr. George P. Robb, New York, addressed the Philadelphia Roentgen Ray Society November 3 on "Visualization of the Cardiac Chambers, the Pulmonary Circulation and the Great Blood Vessels in Man." —Drs. Albert E. Bothe and Jonathan E. Rhoads addressed the Philadelphia Academy of Surgery November 7 on "Treatment of Kidney Tumors" and "Control of Hemorrhage in the Jaundiced Patient" respectively.

### TEXAS

**District Meeting.**—The Thirteenth (Northwest Texas) District Medical Society held a meeting September 13 at Breckenridge. The speakers included Drs. John Edward Johnson, Mineral Wells, "Gastric Failure in Middle Life"; William L. Marr, Galveston, "Treatment of the Anemias"; Truman G. Blocker Jr., Galveston, "Management of the Acute Traumatized Abdomen," and Herman P. Radtke, Fort Worth, "Fracture of the Neck of the Femur Treated by Internal Fixation."

### VIRGINIA

**Society News.**—Dr. Thomas S. Cullen, Baltimore, addressed the Norfolk County Medical Society, Norfolk, October 17 on sewage disposal and stream pollution. —Dr. Robert Finley Gayle Jr., Richmond, was the guest speaker at a recent meeting of the Medical Association of the Valley of Virginia in Staunton on "Treatment of the Psychoneurotic Individual."

**Lectures at the Richmond Academy.**—A series of lectures on the blood has been arranged by the committee on medical education of the Richmond Academy of Medicine. The series is as follows:

Harvey E. Jordan, Ph.D., Charlottesville, Embryology of the Blood, October 18.  
 Rolland J. Main, Ph.D., Richmond, Physiology of the Blood, November 1 and 15.  
 Dr. David T. Smith, Durham, N. C., Immunological Reactions of the Blood.  
 Dr. John H. Scherer, Richmond, Cellular Reactions Occurring in the Blood During Infections.  
 Dr. Frank L. Apperly, Richmond, The Pathologic Physiology of Anemia.  
 Dr. Maxwell M. Wintrobe, Baltimore, The Choice of Methods for the Correction of the Anemias and Why.

### WASHINGTON

**Society News.**—Dr. Herbert F. Traut, New York, addressed the Walla Walla Valley Medical Society, Walla Walla, November 14, on "The Present Status of Endocrinology Related to Gynecological Problems." Dr. Ralph H. Highmiller of the state department of labor and industry presented new changes in the accident fee schedule recently developed with the cooperation of the Washington State Medical Association. —Dr. Arthur M. Shipley, Baltimore, addressed the Spokane County Medical Society, Spokane, November 17 on "Surgical Conditions Involving the Diaphragm." Dr. Herbert F. Traut, New York, addressed a special meeting November 11 on "The Upper Urinary Tract in Pregnancy."

### WEST VIRGINIA

**Committee on Low Cost Medical Care.**—At a special meeting of the council of the West Virginia State Medical Association in Charleston October 2 a committee was appointed to formulate policies concerning prepayment or postpayment medical service plans or bureaus. Drs. Charles W. Waddell, Fairmont, president, and Ray M. Bobbitt, Huntington, president-elect of the state association, appointed the following committee: Drs. Robert J. Wilkinson, Huntington, chairman; John W. Moore, Charleston; Robert J. Reed Jr., Wheeling; Richard O. Rogers, Bluefield; Richard V. Shanklin, Gary, and Philip Johnson, Fairmont.

### GENERAL

**Urological Meeting.**—The Southeastern Branch of the American Urological Association will meet in Louisville, Ky., December 2-3. Among the speakers will be Drs. Herman L. Kretschmer, Chicago, on "Elusive Ulcer of the Bladder: A Critical Review of 110 Cases"; Joseph F. McCarthy, New York, "Prostatic Resection"; Charles C. Higgins, Cleveland, "Stone in the Urinary Tract," and Roger C. Graves, Boston, "Respiration Pyelography."

**Annual Meeting on Prevention of Blindness.**—The annual meeting of the National Society for the Prevention of Blindness will be held in New York December 1. Mr. Lewis H. Carris, managing director of the society, will give an address entitled "Thirty Years in Saving Sight" and the Leslie Dana Gold Medal will be presented to Dr. Ellice M. Alger, New York, who will speak on "Prevention of Blindness from the Ophthalmologist's Point of View."

**Propose Reunion of Workers on Brazilian Railroad.**—The Madeira-Mamore Association, composed of persons who worked on the construction of the Madeira-Mamore Railroad in central and western Brazil from 1907 to 1913, has proposed a reunion of all these workers during the world's fairs in 1939 in San Francisco and New York. Physicians and nurses who are not now members and who care to make themselves known can obtain information from John Y. Bayliss, Richmond, Va., president of the association; Edgar A. Smith, Newportville, Pa., secretary; John H. Armitage, 1205 Russell Road, Alexandria, Va.; Frank S. Jonas, 277 Broadway, New York, chairman of the New York committee, or Charles L. Dimmitt, Redwood City, Calif., chairman of the San Francisco committee.

**Society News.**—The first annual session of the American Medico-Legal Association will be held at the Drake Hotel, Chicago, May 12-13, 1939. Dr. Michel Pijoan, 137 Newbury Street, Boston, is the secretary of the association. —The Pan-Pacific Surgical Association will hold its third congress since its establishment in 1929 in Honolulu Sept. 15-28, 1939. Dr. Forrest J. Pinkerton, Young Building, Honolulu, Hawaii, is the secretary. —The Annual Midwinter Conference of Eastern Radiologists will be held February 10-11, 1939, in Washington, D. C., with headquarters at the Hotel Mayflower. For information, write the secretary of the local committee. Dr. Joseph F. Elward, 1726 Eye Street N.W., Washington.

**Fellowships Available for Research in Chemistry.**—Grants to the total amount of \$25,000 are available through the Lalor Foundation for research in any field of chemistry, according to an announcement. For a reasonable proportion of the awards, preference will be given to candidates "shaping their careers or carrying on research to accomplish a more effective application of the principles and discoveries of physical and organic chemistry upon problems of biochemistry, chemotherapy and pharmacology." The amount of each award will be determined on the basis of previous training, ranging usually between \$1,800 and \$2,500. Attainment of the Ph.D. degree or its equivalent in training is a requirement, but there are no other limitations as to age or residence. Inquiries and requests for application forms should be addressed to C. Lalor Burdick, secretary, Lalor Foundation, Wilmington, Del. The Lalor Foundation was established in 1935 for support of scientific research and has administered twelve fellowships. Applications must be filed by December 31.

**Tri-State Meeting.**—At the thirty-third annual meeting of the Tri-State Medical Society at the Grim Hotel, Texarkana, October 26-27 Dr. Joseph D. Roberts Jr., Longview, Texas, was elected president. The following were made vice presidents: Drs. Stanley George Wolfe, Shreveport, La.; Arley D. Cathey, El Dorado, Ark., and Richard G. Granbery, Marshall, Texas. Dr. Robert K. Womack, Longview, was elected secretary. The scientific program included:

- Dr. Walter G. Reddick, Dallas, Sulfanilamide in General Medicine.
- Dr. Stanley George Wolfe, Shreveport, La., Undulant Fever.
- Dr. Robert Lee Sanders, Memphis, Tenn., Surgical Treatment of Gallbladder Disease.
- Dr. Henry Gordon Rudner, Memphis, Synopsis of Medical Treatment of Gallbladder Disease.
- Dr. J. L. McGehee, Memphis, Preoperative and Postoperative Care of Abdominal Surgical Conditions.
- Dr. Oscar W. Bethea, New Orleans, A Study of the Status of New Drugs.
- Dr. Edward L. King, New Orleans, Diagnosis and Treatment of Cervical Dystocia.
- Dr. Lewis J. Moorman, Oklahoma City, Difficult Problems in Diagnosing Chest Conditions.
- Dr. Lee B. Harrison, St. Louis, Cardiovascular Syphilis.

**Western Surgical Association.**—The forty-eighth annual meeting of the Western Surgical Association will be held in Omaha December 2-3 with headquarters at the Hotel Fontenelle. The guest speaker will be Dr. William Boyd, Toronto, Canada, on "Tumors of the Neck." Among other speakers will be:

- Drs. Waltman Walters and Albert M. Snell, Rochester, Minn., Hemorrhagic Tendency in Jaundice, with Special Reference to Its Treatment with Vitamin K.
- Dr. Neil J. MacLean, Winnipeg, Man., An Improved Incision for the Radical Operation for Carcinoma of the Breast.
- Dr. George B. Packard, Denver, Indications for Splenectomy in Children.
- Dr. Henry W. Meyerding, Rochester, Minn., Diagnosis and Treatment of Ewing's Tumor.
- Dr. Stanley J. Seeger, Milwaukee, Technical Notes on Pediatric Surgery—(1) Hypertrophic Pyloric Stenosis and (2) Congenital Indirect Inguinal Hernia.
- Drs. George M. Curtis and Frank E. Hamilton, Columbus, Ohio, The Surgical Significance of the Motor Activity of the Human Stomach.
- Dr. Owen H. Wangenstein, Minneapolis, Experiences with Employment of Suction in the Treatment of Acute Intestinal Obstruction.
- Dr. William T. Coughlin, St. Louis, The Repair of Pharyngeal and Laryngotracheal Fistulae.

Dr. Casper F. Hegner, Denver, is president of the association.

**Special Society Elections.**—Dr. R. Wallace Billington, Nashville, Tenn., was elected president of the Clinical Orthopedic Society at its annual meeting in Nashville and Birmingham, Ala., October 7-8. Dr. Dale Wilson, Toledo, Ohio, was made vice president and Dr. H. Earle Conwell, Birmingham, secretary. Next year's meeting will be held in Little Rock, Ark., and Oklahoma City in October.—Dr. John C. McKinley, Minneapolis, was elected president of the Central Neuro-psychiatric Association at its annual meeting in Minneapolis October 7-8; Dr. Groves B. Smith, Godfrey, Ill., was made vice president and Dr. William C. Menninger, Topeka, Kan., secretary.—Dr. Herbert B. Wright, Cleveland, was made president-elect of the Aéro Medical Association at the recent annual meeting in Dayton, Ohio, and Dr. James C. Cole, New Orleans, was installed as president. Vice presidents at large elected were Capt. Harry G. Armstrong, Wright Field, Dayton; Drs. Richard H. Hoffman, Bellefonte, Pa.; Eldridge S. Adams, Washington, D. C., and Giles A. Coors, Memphis. Dr. Herbert F. Fenwick, Chicago, was elected first vice president and Dr. David S. Brachman, Detroit, reelected secretary.—At the thirty-ninth annual session of the Seaboard Airline Railway Surgeons Association in Richmond October 13-15 the following officers were elected: Drs. Arthur R. Beyer, Tampa, Fla., president; Joseph O. McClelland, Maxton, N. C., Robert O. Lyell, Miami, Fla., and Wilbur R. Bracey, Richmond, vice presidents, and Jarrett W. Palmer, Ailey, Ga., secretary.

## CANADA

**Professor Marrian Goes to Edinburgh.**—Guy F. Marrian, D.Sc., professor of biochemistry, University of Toronto Faculty of Medicine, Toronto, has been appointed to the chair of chemistry in relation to medicine at the University of Edinburgh. Professor Marrian was born in London in 1904 and educated at University College, London. After obtaining his doctor's degree in 1930 he was lecturer in the department of physiology and biochemistry at University College until 1933, when he received a William Julius Mickle fellowship from the University of London and went to Toronto as assistant professor of biochemistry. He was made a full professor in 1936.

**Society News.**—Dr. Frank A. Turnbull addressed the Vancouver Medical Association, Vancouver, October 4 on "Pituitary and Parapituitary Tumors."—Sir Edward Mellanby, secretary general of the Medical Research Council of Great Britain, gave an address at the University of Toronto October 5 under the auspices of the Canadian Medical Association. His subject was "Nutrition—Its Importance to the Individual and the Nation."—Dr. John Alexander, Ann Arbor, Mich., addressed the Academy of Medicine of Toronto November 1 in a joint meeting with district 11 of the Ontario Medical Association on "Management of Abscess of the Lung."

## Deaths in Other Countries

Sir Robert J. Johnstone, Newcastle, president of the British Medical Association in 1937, died October 26.—Dr. David Bruce Stewart Bruce-Jones, senior medical officer of the Canadian Pacific Steamship Line, died in London November 1.

## Government Services

### Training in Pathology and Diagnosis of Tumors

The surgeon general of the U. S. Public Health Service announces that, in order to meet the need for pathologists skilled in the diagnosis of tumors, special consideration will be given in making appointments for training under the provisions of the National Cancer Institute Act to qualified pathologists who wish to obtain additional training in diagnosis and pathology of tumors.

### Monthly Meeting of Navy Officers

Dr. Esmond R. Long, director of the Henry Phipps Institute of the University of Pennsylvania, Philadelphia, addressed the first monthly meeting of this season of the medical and dental officers of the navy at the Naval Medical School, Washington, D. C., October 10, on "The Use of Tuberculin in the Diagnosis of Tuberculosis."

### Residencies Open at St. Elizabeths Hospital

The U. S. Civil Service Commission announces open competitive examinations for internships and residencies at St. Elizabeths Hospital, Washington, D. C. It is expected that there will be two vacancies July 1, 1939, and two Oct. 1, 1939, for junior medical officers in rotating internships of two years; during the fiscal year beginning July 1, 1939, there will be five vacancies for psychiatric residents, graduate internships offered to graduates in medicine who have served an accredited internship. Applicants should state definitely whether they are applying for the rotating internship or the psychiatric residency. Entrance salaries are \$2,000 a year; if permissive legislation already proposed is passed by Congress, however, the salary of interns may be \$600 a year. All interns are required to live in the hospital and there are no quarters for the families of married interns. Applicants for the internships must be fourth year students in a grade A medical school and those for the residencies must have graduated from a grade A school and must have completed an internship of at least one year. Candidates must not have passed their fortieth birthday on the date of the close of receipt of applications. They will not be required to report at any place for examination but will be rated on the extent of their education and on the extent and quality of their experience. The closing date is December 13 for all except eleven states in the Far West, from which applications will be received until December 16. Forms may be secured from the Secretary, Board of Civil Service Examiners, at any first class post office, from the commission at Washington, D. C., or from any district office of the commission.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Oct. 29, 1938.

#### Gas Masks for Babies and Young Children

Nearly two million gas masks for babies and young children are in course of construction. The problem of providing protection for them from gas attacks has proved difficult. They are being made in two sizes, one for children under the age of 2 years, the other for those between the ages of 2 and 4 years. Those for the older children are similar to adult civilian masks, but the uncomfortable straps are replaced by a neat rubber headpiece. Delay has been caused by the many experiments necessary before a suitable filter could be found through which children could breathe with ease. The masks for babies of 2 and under are an entirely British invention and have been designed differently from the ordinary mask. They fit over the baby's body and are secured between the legs.

#### The Danger of Naval Hospitals at Naval Centers

A correspondent of the *Times* points out that the chief naval hospitals are situated in important naval centers and that they might be seriously damaged in the event of bombardment or air attack. He therefore suggests that, in view of the difficulties of evacuating casualties by road or rail, hospitals should be placed in positions on the coast distant from any naval or military objectives, so that the transport of casualties might easily be effected by means of the small pleasure steamers at present to be found in holiday resorts. Such hospitals could be used as youth hostels in time of peace and readily converted to their purpose should hostilities begin.

#### Evacuation of Populous Areas in War

It is unfortunately true that war now means attacks on the civilian population of towns and cities. The government appointed a committee to consider the question of evacuation of populous areas in war and has accepted its report. The committee says that the whole issue in any future war may well turn on the manner in which evacuation from densely populated industrial areas is handled. People will be much safer in rural districts or in small country towns than in the heart of London. A thinning of the population of urban areas will relieve the pressure on essential services which might prove insufficient. In the event of an exodus, whether planned or forced by repeated air attacks, men and women engaged on essential work would in the great majority of cases be moved by a sense of duty to continue their tasks. The tendency to migrate would be especially among those who can be spared. The country will not be fully prepared until schemes of evacuation have been worked out for the main industrial centers and the necessary organization has been set up. The schemes must be on a basis of voluntary evacuation. Compulsory evacuation would arise only in limited areas subject to intensive bombardment or because of flooding or other reason they had become uninhabitable.

In the London area there appear to be adequate transport facilities for evacuation on any practicable scale. The main line railways would be fed by underground railways and busses. It is calculated that persons could be removed from London at a rate of 100,000 an hour. The refugees would have to be housed in private dwellings under a scheme of compulsory billeting. The Ministry of Health has assumed, as a rough basis for calculation, that five persons could be accommodated in every four rooms. A scheme of voluntary billeting is considered impracticable, but in the case of school children it would be an advantage if they were received as far as possible in houses that had expressed willingness to receive them. No serious difficulty is anticipated in feeding refugees provided arrangements are made in advance. Welfare services will be required and will offer a great scope for voluntary work. Chil-

dren should be transferred school by school and have the first claim on transport. The public should be educated in any scheme decided on.

#### The Destruction of Mosquitoes Carried by Airplanes

The possibility of airplanes introducing diseases into a country by carrying insect vectors from a place where it is rife must be provided against. Indeed, it has been stated that a new type of malaria was brought from Africa to Brazil in this way. There is now anxiety whether yellow fever, which has heretofore been confined to tropical America and Africa, will be transplanted to Asia. Imperial Airways maintains a research station in London, and experiments have been made there with a practically odorless and colorless vapor which is distilled from an English wild flower, pyrethrum, specially cultivated for the purpose. About 200 mosquitoes, all potential vectors of disease, were supplied by the London School of Tropical Medicine. The liquid distillate from the pyrethrum was poured into an atomizer constructed for use in aircraft, which was used in a room of about twice the capacity of the imperial flying boats. In seven minutes, about half the time during which the atomizer would be used on aircraft, all the insects were dead. The vapor is harmless to man but it will also kill the tsetse fly, the vector of trypanosomiasis. All countries through which Imperial Airways operates have regulations for preventing the carriage of disease by insects, but their regulations differ. It is hoped that international recognition of the method will be obtained.

#### The Need for a New Unity in Medicine

Opening the new medical school of the University of Aberdeen, Lord Dawson said that curative and preventive medicine were separated too much. At present preventive medicine was inadequately taught and was nothing but a postscript to the student's career. In recent years there had been a gradual growth of medical services and hospitals which, however individually excellent, were a medley of separate efforts. They fell under three headings: (1) communal services and clinics, (2) voluntary hospitals and (3) municipal hospitals. The communal services represented a fine achievement but had the serious defect of isolation and divorce from the general body of physicians in their district. The voluntary hospitals were centuries old and had grown up with the British people. To allow them to become absorbed by the local authorities into their municipal hospitals would be alien to our social evolution and a damage to our well being. But they could not stand as disconnected institutions and must play their part in a comprehensive scheme of medical services. They could not claim that the possession of teaching schools conferred the right to exclusiveness, for teaching had been extended to the communal clinics and municipal hospitals. The latter had come into existence during the last eight years and had steadily grown in numbers and importance. They were serving the community well but they should cooperate with the voluntary hospitals. Two sets of hospitals and two sets of doctors working independently would produce only confusion and conflict.

#### A "Trial Year" for Student Nurses

As stated in previous letters, the hospitals have difficulty in obtaining a sufficient number of nurses. The arduousness and restrictions of the profession deter girls from entering it. In some hospitals, hours of work have been reduced in order to increase the attraction. The West London Hospital has brought forward an entirely new scheme. Heretofore hospitals have not, as a rule, received girls for training under the age of 18, and a large number who leave school at 17 have to fill in a year before entering a nursing career. The West London Hospital proposes to fill this gap by providing training for girls as non-resident students who can get the hospital atmosphere and learn much of the work of the nurse. They will live at home and will wear overalls, not the nurse's uniform, at the hospital. There will be no restriction as to the use of cosmetics other than

good taste. At the end of the period the student will be free to decide whether she wishes to adopt the nursing career. Even if she does not she will not have wasted her time, for she will have learned much that is of practical use. The maximum hours of attendance will not exceed thirty in a five day week. Dinner and tea will be provided. Lectures will be given in the morning on hygiene, anatomy and physiology, invalid cooking, chemistry of foodstuffs, first aid and nursing. At the end of the course the students will sit for an examination and, if successful, will be accepted as probationers. At times some of the students will be admitted to the wards under the supervision of the sisters, but they will not be brought in contact with cases unsuitable for girls of their age.

## PARIS

(From Our Regular Correspondent)

Oct. 29, 1938.

### Annual Meeting of French Surgical Association

This year's congress of the French Surgical Association was held in Paris October 17-22, the date having been changed from October 6 on account of the recent international complications. The president of the present congress was Prof. Leon Imbert of Marseilles and the secretary was Professor Brocq of Paris.

#### TREATMENT OF RECENT CLOSED FRACTURES OF THE SPINE

The first subject chosen for reports and general discussion concerned the treatment of recent closed fractures of the spine. Drs. Charbonnel of Bordeaux and Sicard submitted the chief report on this question. Dr. Charbonnel's paper aimed to include only fractures of the bodies of the vertebrae without nerve complications. One's first duty is to attempt to educate the public how to transport a person whose spine is fractured. A great deal of harm may follow lifting the injured person by the shoulders or lower extremities. The best method is to place the patient face downward on a plank, a stretcher or a blanket supported at its four corners. If the injured person is found lying on the side or back, the utmost care should be taken in rolling him so as to place him face downward. Spontaneous reduction may take place if first aid is correctly applied. With the aid of a portable x-ray apparatus, films should be exposed without the patient being moved from his bed, as soon as possible after admission to a hospital. Both anteroposterior and lateral exposures must be made in order to give the surgeon essential information regarding the fracture. Both of the exposures can be made without the injured person being moved. Most frequently the dorsolumbar region, from the eleventh dorsal to the second lumbar vertebra, is involved. Even though the fracture be at a lower level, from the third to the fifth lumbar vertebra, the treatment is the same.

Based on a study of 217 cases without nerve complications, the results of the application of various nonoperative and operative methods show that the following conclusions can be drawn: The method of reduction termed hyperlordosis as advocated by Böhler should be employed as soon after the accident as possible. It aims only to place the upper and lower surfaces of the vertebrae parallel rather than to attempt to secure complete anatomic reduction. Many prefer placing the patient on the back rather than in the ventral position while reducing the fracture. No case has so far been reported of any serious nerve complication following the use of this method of reduction. The duration of the immobilization after reduction depends on the gravity of the fracture and the age of the patient. The Magnus method of permitting the patient to sit up in bed after four weeks and then encouraging him to walk unaided after six weeks of confinement to bed is applicable only to fractures with slight displacement and then only if the patient is under constant surveillance. The complete immobilization methods formerly employed are indicated at the present time only when the spinal injury is complicated

by fractures of the extremities. Even when the nonreduction method is used, a plaster cast in a position of lordosis followed by early physical therapy is indicated. Operative methods such as the use of bone grafts are seldom used for fractures of the spine without nerve involvement because the results are not as satisfactory as with the Böhler method of early reduction for fractures in the dorsolumbar region. The use of bone grafts at an early period is to be recommended only in comminuted fractures of several adjacent vertebrae, oblique fractures which show rapid displacement following early reduction and plaster cast, and so-called fracture-dislocations without nerve complications, if orthopedic methods are unsuccessful.

#### TREATMENT OF FRACTURES OF THE SPINE WITH NERVE COMPLICATIONS

The second half of the report was presented by Dr. Sicard of Paris. As to the relative frequency of spinal fractures with nerve complications, he had been able to find 195 cases, or 42 per cent, of fractures with nerve complications as compared to 467 without such a complication. Nerve lesions are most common in fractures involving the last cervical and first few dorsal vertebrae. At present, no clinical sign is pathognomonic of a complete involvement of the spinal cord. A complete, flaccid paralysis, the Babinski sign in extension, the defensive reflexes and the law of Bastian all lack absolute value. Histologic study of traumatic cord lesions teaches that the spinal cord does not possess the property of regeneration. Only three clinical signs can give an approximate evaluation of the severity of the lesions. These are (a) early and persistent priapism, (b) early edema of the lower extremities and (c) the rapid appearance of trophic changes such as decubitus over the sacrum or heels. When these are observed within a few days after the injury, they indicate complete destruction of the cord.

Some surgeons believe that, if the cord is destroyed, operative intervention is of no avail. If there is some lessening of the paralysis, efforts to maintain the integrity of the muscular and joint systems are all that are indicated. Others advocate immediate reduction, hoping that the decompression will lessen the damage to the cord, or they recommend laminectomy as a routine procedure. A third group has no fixed plan but tries to combine different methods of treatment. The conclusions of the author were that no treatment is of any avail if the cord is completely divided. The only hope of any improvement is that the symptoms may be only the result of an edema. Between these two extremes of opinion as to treatment one should not remain inactive in a case of fracture of the spine, complicated by paralysis, contrary to former teaching. The lesion should be regarded as curable and treatment begun as early as possible, either by reduction of the fracture or by laminectomy, the only contraindications being the existence of severe shock or the necessity of caring for a more urgent injury. In partial paralyses, reduction is always to be recommended, controlled at intervals by radiography and supplemented by early physical therapy. In complete paralyses, especially of the spasmodic type, reduction is followed by rapid recession of symptoms. If the paralysis is of the flaccid type, it is more difficult to decide on the indications. The most reliable diagnostic method is radiography. The presence of a bone fragment in the spinal canal, persisting after reduction, calls for laminectomy. Operation is indicated also if the articular processes are impacted. In general, if no amelioration of symptoms has taken place in from eight to fifteen days an exploratory laminectomy is justifiable. The higher the level of the fracture with nerve complications, the less favorable the prognosis. A flaccid paralysis is always to be regarded as a grave sign, indicating irreparable lesions.

The discussion was opened by Dr. Schotte of Ghent, Belgium, who advocated early reduction in the dorsal position.

In the treatment of cases with nerve root symptoms the first step should be epidural or paravertebral anesthesia in order to exclude cases of a purely functional character, so frequently encountered in malingerers in industrial surgery. Dr. Charles Mayer of Brussels, on the basis of a follow-up study of eighty-six personally observed cases, seventy without and sixteen with nerve complications, believed that orthopedic reduction can be regarded as a decided step in advance especially in cases with nerve complications. In the absence of such symptoms, reduction is indicated if the film indicates a crushing injury involving more than a fourth of the height of the vertebral body, especially in younger persons. If orthopedic reduction is correctly employed, indications for the use of bone grafts will rarely be encountered. Laminectomy should be done if the signs of cord injury appear late or recur after temporary recession. Dr. Lambret of Lille also endorsed the efficacy of early reduction as advocated by Böhler. Professor Leriche of Strasbourg said that there is no disagreement as to the value of immediate reduction in cases of moderate severity but that there is a divergence of opinion as to its application in the severe type. In the latter, if the nerve complications do not improve after reduction, immediate laminectomy is indicated, preceded by cystostomy to prevent kidney infection following catheterization.

#### STAPHYLOCOCCIC SEPTICEMIA

The second question for reports and general discussion was the clinical forms and treatment of staphylococcic septicemia. Dr. Jean Patel of Paris placed the staphylococcic septicemias as observed clinically in three groups, the acute, subacute and chronic forms. The first of these includes two subgroups. In the first the clinical picture is that of an acute infection in which it is impossible to find an atrium, a diagnosis becoming possible only after positive blood and urine cultures. In the second subgroup the general symptoms are as marked as in the first subgroup but a local lesion such as a furuncle, especially one on the lip or in the nose, precedes the onset of the symptoms of septicemia. In some cases in this second subgroup, after two or three days of severe general symptoms an acute osteomyelitis or multiple skin localizations attract attention to the existence of a general staphylococcic infection. In the second main group, the subacute, the clinical picture of a generalized sepsis shows signs of recession at a time when evidences of metastatic infection, in the form of osseous, articular, muscular, cutaneous and even pulmonary or renal foci, appear. In the third principal group, the chronic form of staphylococcic septicemia, the patient gives a history of recurrent staphylococcic localization in the form of furuncles, pulmonary or perinephric abscess or suppurative prostatitis.

As to the laboratory side of the question, animal experiments fail to reproduce the clinical pictures. The staphylococcus is carried by way of the veins, and inoculation of animals is followed by rapid metastatic foci. The staphylococcus secretes a toxin which possesses lethal properties toward all the cells of the body, although giving rise to the rapid formation of an antitoxin. The staphylococcus, far from being destroyed by the leukocytes, retains its virulence and is transported by the white blood cells through the venous circulation to the right ventricle, then to the lungs and left ventricle, and finally to the systemic circulation. The defensive agents are the opsinins and lysins, less often the leukocytes. The clinical picture is due to the direct action of the bacteria rather than to their toxin, except in the case of necrotic lesions which are the result of the action of the toxin.

The treatment of staphylococcic septicemia was the subject of a report by Dr. Moiroud of Marseilles, who reviewed the nonoperative measures, placing them in three principal groups. The first includes transfusions, which can stimulate blood formation and phagocytosis. As to immunotransfusions, their value is not settled. Although some favorable results have

been obtained in some cases, in many others immunotransfusion has failed. The danger of shock and of dissemination of the infection as the result of transfusions of any form, must not be overlooked. The shock (foreign protein) treatment appears to be rational but is not to be recommended because of the danger of starting up a true septicemia. The same criticism can be made of the use of vaccines and of toxoids, the latter recommended by Ramon. If staphylococcus toxoid is employed, a preliminary test should always be made of the sensitivity of the patient. The bacteriophage treatment should be used only locally because the intravenous injection may be followed by serious symptoms. Chemotherapy, the use of acriflavine hydrochloride or mercurochrome, has given some good results if these products are employed in very minute doses. The operative treatment aims to clear up the atrium of infection but often it is impossible to find one.

The discussion was opened by Prof. Robert Debré, who stated that a true staphylococcic septicemia is rare as compared with transitory bacteremias, which are common. Recent studies show that the staphylococcus acts as the result of formation of a toxin rather than because of its virulence per se, and hence more is to be expected by giving specific antitoxins and toxoids than from any other treatment.

#### The Development of Neuroses

The last few decades of medical research have taught us to revise our concepts of the neuroses. The diagnosis of "psychopathies" of various types is purely descriptive. On the other hand the concept of neuroses, which has grown up around psychotherapeutic experience, takes into account the many predisposing factors which underlie a manifestation of abnormal psychic development and reactivity, and hypothesizes that, granted correspondingly favorable circumstances, many neurotic persons would have remained healthy. Accordingly, it is considered that through psychotherapy one afflicted with a neurosis may be restored to mental health. The entire problem was recently summarized by Prof. J. H. Schultz, Berlin neurologist, who is thoroughly conversant with the field and who is the author of several books on neurosis. The hypothesis of heritability and improvement remains uncorroborated by genetic research; severe congenitally characterologic deficiencies are not classified as neuroses. A special difficulty in the field of neuroses lies in the fact that identical clinical syndromes may be based on wholly disparate anamneses. It is therefore impossible to establish a distinctive pathology of the nervous disturbances of heart action, speech, sleep, volition and so on. Rather an attempt must be made to identify the neuroses according to their development and to determine the "principal psychologic field of its source."

A classification of the neuroses, suggested by the author, is here of further assistance.

Since a neurosis or psychopathy is to be considered a developmental disturbance, a defective and morbid adaptation to life, all possible fundamental causes of such a maladjustment should be passed in review. Schultz places in his first category mental disturbances in which the patient has been completely dependent on another sick or otherwise afflicted person. For example, if the infant of an abnormal or inferior mother reacts to the situation by neurotic manifestations it is plainly not the child but the mother who requires treatment. The child should be transferred to a wholesome milieu, where in a brief time it will become normal. The neuroses (of the children) in such cases are termed by Schultz fremdneurosen (exogenic neuroses); they are produced exogenically and based on allopsychic conflicts. In such cases it is not at all a question of special individual psychotherapy but of active supervision and above all change of environment.

Then there are the neuroses of bad habit, for example, nictitation based on childhood conjunctivitis with photophobia. Schultz says that these neuroses are physiogenic and as they are situated to a certain extent on the borders of personality he terms them *randneurosen* (marginal neuroses). For this group a complicated treatment based on a profound study of the personality is superfluous and useless; a simple active therapy will suffice.

It is otherwise with those neuroses which, psychogenic in the usual clinical sense, are based on normally experienced emotions such as grief, distress, anxiety or jealousy. As the "middle strata" of the psyche are disturbed in the neuroses Schultz terms them *schichtneurosen* (stratum neuroses). These originate (preponderately) in endopsychic conflicts. Various methods of therapeutics, none of which may be called genuine psychotherapy, are here applicable.

On the other hand, major psychotherapy is indicated only in the really severe neuroses. Since in the latter the "nucleus" of personality is altered, Schultz terms them the nuclear neuroses. It is possible to be affected with an exogenic, a marginal or a stratum neurosis and still retain a fairly sound general personality. But in a characterogenic nuclear neurosis the entire personality "has been" neurotically deformed from earliest childhood and a state of autopsychic conflict has been constantly present. In such cases the personality of the patient must be gradually reeducated, consciously and subconsciously, through a painstaking course of profound psychotherapy, which will need to continue for months or years. Schultz warns against a summary exclusion of the possibility of a nuclear neurosis in cases which present bronchial asthma, insomnia, anxiety states and so on; this is often done because the manifestations appear "too mild." Such symptoms may mask a deep-seated nuclear neurosis of wide ramifications. If a neurosis remains refractive to minor psychotherapeutic measures, it must never be concluded that psychic factors are not present; rather, says Schultz, an approach by major psychotherapy should be essayed whenever feasible.

#### Insurance of Health of Workers

The Italian journal *Difesa Sociale* recently published statistics on the clinical and social work which has been carried on by the Istituto della Previdenza Sociale during the last year on laborers. The department of insurance against tuberculosis began functioning in 1929. During the year 9,345 persons were given medical care in hospitals of the department. Every year the number of those who are cared for by the department increases. The insurance against tuberculosis protects peasants as well as laborers. New hospitals and sanatoriums have been made available and the laboratories for diagnosis have been properly equipped. The department cared for 37,099 insured persons or members of their families in 1936 and 44,420 in 1937, with a total number of 8,565,023 days of hospitalization for the whole group.

The department of insurance against invalidism sent 15,796 insured persons or members of their families in 1936 and 20,720 in 1937 to have treatments at balnearies of mineral waters. The department manages fourteen balnearies, four of which are the property of the department. In the course of 1937, 4,997 convalescents of diseases which may cause invalidism were sent to sanatoriums for convalescents which are run by the department, with a number of days of sojourn of 141,746 for the whole group. The Institution for Social Providence has fifty-three trachoma dispensaries for both insured and noninsured persons. There were 24,500 trachomatous patients who were observed and treated in 1937. Consultations and treatments numbered about 1,265,445. The insurance to protect motherhood covers peasant women as well as laboring women. The department has seventeen offices for consultation, in which about 27,614

consultations from about 10,429 were given in the course of 1937. The mothers are cared for in the course of pregnancy, labor and the puerperium and are given guidance with regard to nursing their babies.

#### Temperature and Pulse of White People in the Tropics

Dr. Semmola, lieutenant of medical officers in Somaliland, took the temperature and determined the pulse rate in 600 normal healthy Italian soldiers in Somaliland. They have lived for some time in tropical zones under good hygienic conditions and they are well protected against the severity of the climate. The determinations were made early in the morning and at noon. The atmospheric temperature varied between 86 and 95 F. The humidity was between 60 and 70 per cent. The axillary temperature was above 98.6 F. in 28 per cent of the cases, but the subjects were in normal health. The author believes that the temperature of the body of normal white persons is physiologically increased in tropical lands and that the increase has no pathologic significance. The pulse rate in tropical lands is normal in the morning (from 70 to 74 beats a minute) and increased at noon (from 80 to 84 beats a minute).

#### Arterial Blood Pressure in Diseases of the Eye

In the Ophthalmologic Clinic of Warsaw University Professor Lauber and Dr. Sobański have found that serious disorders of the eye can be due to a disproportion between blood pressure and intra-ocular pressure. The disproportion can result from an increase of intra-ocular pressure or from a decrease of blood pressure. The imbalance of both these pressures may cause an insufficient supply of blood to the retina and to the optic nerve. This phenomenon is exemplified in the development of optic nerve atrophy in *tabes dorsalis*. In this disease, optic nerve atrophy progresses gradually as the blood pressure sinks and stops or progresses more slowly when the blood pressure increases. Constitutional arterial hypotension or hypotension caused by antisyphilitic therapy provokes a greater involvement of the eye in tabetic patients. Hypotension in the retinal arteries was found not only in *tabes dorsalis*, but also in many "idiopathic" cases of atrophy of the optic nerve and in pigmentary degeneration of the retina. These facts are important in the therapy of *tabes dorsalis* for controlling atrophy of the optic nerve. In every case of *tabes dorsalis* the proportion of the arterial to the intra-ocular pressure has to be controlled either by increasing the former or by decreasing the latter. The decrease of intra-ocular pressure is more safely and easily obtained than is an increase of blood pressure. In every case the authors instilled pilocarpine or physostigmine and, if its effect on the intra-ocular pressure was not sufficient, cyclodialysis was performed. After the prevention of eye involvement, antisyphilitic treatment was begun. The effect of antisyphilitic therapy on blood pressure has to be constantly watched and in case of a great decrease of blood pressure it has to be stopped. The authors suggest that in most cases of *tabes dorsalis* serious eye complications can be prevented if adequate prophylactic measures are taken.

#### The Number of Physicians in Poland

According to the official report of the Polish Medical Chamber, the total number of physicians practicing in Poland was 12,215, or one physician for 2,833 inhabitants. The percentage of Jews among the physicians is about 33.4, while Jews are only 9.6 per cent of the whole population in Poland. Among the chief causes of deaths of physicians in the last year were cardiovascular diseases 40.5 per cent, tuberculosis 17 per cent, malignant tumors 13 per cent, epidemic diseases 8 per cent and suicide 4 per cent.

### Tuberculosis in Children

Dr. T. Mogilnicki read a paper before the Warsaw Pediatric Society on the incidence of tuberculosis in children in Poland. His data are based on researches on tuberculosis in various districts in children in the elementary and high schools, in nurseries and in children from 1 to 6 years of age. In the schools attended by poor children the Pirquet test was positive in 38 per cent in children of 6 and in 44 per cent in children of 7 years, while in schools attended by rich children the Pirquet test was positive in 18 per cent in children of 6 and in 19 per cent in children of 7. In the Jewish children the percentage of positive Pirquet tests was higher by more than 10 than in Christian children. This test is more frequently positive in children in large cities than in rural children in the West of Poland. In the East of Poland, where the financial conditions of the rural population are worse, the Pirquet test is more frequently positive in the country than in cities. The author determined the total number of tuberculous children in Poland to be about 370,000. The tuberculosis mortality of children at the age of 1-5 years is high in Poland, being 38 per cent as against 5.7 in Germany, 5.0 in Denmark, 15.0 in Estonia, 12.0 in France, 8.2 in Norway and 7.3 in Sweden per 10,000 of the population of this age. These researches on tuberculosis in children have shown that the most frequent source of infection is tuberculous persons in the environment of the children. The author believes that the poor state of health of the young generation in Poland is mainly due to an inadequate campaign against tuberculosis by the government, resulting from inadequate funds. He urges the x-ray examination of school children and teachers in order to isolate the tuberculous subjects as sources of infection and to be able to start treatment in early stages of the disease.

### The Medical Congress

Last month the Medical Association of South Africa (British Medical Association) held its thirty-second medical congress at Lourenço Marques, Portuguese East Africa, for the first time in its history beyond the borders of the Union of South Africa. The meeting was held at the invitation of the health services of Mozambique and under the patronage of the Portuguese minister for colonies, Dr. Francisco Viera Machado. It was an unqualified success and was attended by doctors from the Union of South Africa, Rhodesia, Angola and the Portuguese colonies. Thus there was an opportunity to discuss matters of common interest. An attractive program of entertainment, including native dances, open air fetes and excursions to the game reserves, somewhat interfered with the excellent professional program, but the sectional and plenary meetings were well attended and the discussions, in Portuguese and English, were animated and instructive. From the old Portuguese universities of Coimbra and Lisbon, delegates attended, among them being the deans of faculties of medicine, who contributed interesting papers. The president of the congress was Dr. Vasco Palmeirim, chief of the local department of health, and the organizing secretary was Dr. Abel de Carvalho, a local radiologist. Among the most interesting papers were those on malaria by Professor Froilano de Melo of Nova Goa, on heliotherapy by Professor Grober of Jena, on bronchopulmonary suppuration by Dr. Nunes de Almeida of the Instituto Portugues de Oncologia of Lisbon, and on the extracardiac arteries in the circulation of the myocardium by Prof. Maximino Correia of Coimbra. The discussions on the nutritional problems of the natives were interesting, while one plenary session was devoted to discussion of the treatment of peptic ulcer, the consensus favoring conservative treatment as against gastrectomy and emphasizing that gastric and duodenal ulcers are not merely local lesions. Another instructive session was devoted to com-

parative medicine. Since 1928 the medical association has invited the veterinary surgeons to participate in the congress, and the combination has been mutually advantageous. At this congress Dr. Gilles de Kock of the research institute at Onderstepoort, which is associated with the memory of Sir Arnold Theiler, contributed a paper on the role assumed by game and wild animals in the spread of human disease. Both the Union of South Africa and Mozambique are keenly interested in their game reserves. The present outbreak of foot and mouth disease and the possibility that the larger antelopes and wild bovines might be carriers of disease enhanced the interest in the discussion. A second paper, on the risks of introducing yellow fever by airplanes, was read by Dr. Park Ross, who demonstrated his method of disinfection by means of a special spray. The next congress will be held at Port Elizabeth next year but will be overshadowed in importance by the congress of 1941, when the British Medical Association will hold its annual meeting, jointly with the South African Association, at Johannesburg. An organizing committee has already been appointed to make preliminary arrangements for that meeting.

### Rickettsiosis

Pijper and Crocker, from the former's private laboratory at Pretoria, have made an intensive study of rickettsiosis in South Africa, the results of which they have published. The three types—tick bite fever, murine or rat flea or sporadic typhus, and louse typhus—prevalent in the country are considered to be a group by themselves. They have come to the conclusion that South African typhus is not identical with classic typhus from their extended study of the serologic differences in the agglutinin titers of a large number of rabbits infected with the Basutoland strain of epidemic typhus. They found a sporadic typhus virus immunologically identical with a virus in rats that protected against tick bite fever but not against epidemic typhus. This sporadic form of typhus dies out in guinea pigs when brain injections are used, while the epidemic form can be kept indefinitely by this method.

### Smallpox and Amaas

The relationship between smallpox and the type of it locally known as amaas, which appears to have affinities to the type known in Europe as alastrim, has long been a matter of controversy. A posthumous paper by Dr. George Hay is devoted to the clinical and epidemiologic features of amaas. The author concludes that the natives penetrated into the northern Transvaal in two separate streams, which have not intermingled until recent times. The southern group shows evidence of infection by genuine classic smallpox; the northern group shows signs of infection by a smallpox-like disease that leaves little scarring and disfigurement. Both types are readily controlled by vaccination, but the author suggests that the vaccine used should contain strains of both types, particularly that of the light or amaas type. Vaccination, although compulsory by law, has been much neglected, with the result that the non-immune population is rapidly increasing.

## Marriages

- PAUL LE ROY MARTIN, Skykomish, Wash., to Miss Evelyn Rosetta Goodenough, July 24.  
ROBERT E. NELSON to Miss Margaret Hoffman, both of Harrington, Wash., August 26.  
EDWIN G. LEE, Colfax, Wash., to Miss Elrina Ellerbrock of Los Angeles, July 12.  
VERNE W. RITTER to Mrs. Blanche Bullock Burns, both of Seattle, August 6.  
EDWIN S. WEISFIELD to Miss Mildred Schonfeld, both of Seattle, August 4.  
TAMARA J. KABALKIN, Seattle, to Mr. Arthur Sternoff, July 15.

## Deaths

**Patrick Eugene McSweeney** ☉ Burlington, Vt.; University of Vermont College of Medicine, Burlington, 1886; past president of the Chittenden County Medical Society and the Vermont State Medical Society; adjunct professor of obstetrics at his alma mater, 1895-1914, instructor of gynecology, 1900-1903, professor of gynecology, 1911-1925, professor of obstetrics, 1914-1925, and since 1925 emeritus professor of obstetrics and gynecology; member of the New England Obstetrical and Gynecological Society and the New England Surgical Society; fellow of the American College of Surgeons; attending surgeon to the Bishop de Goesbriand Hospital, Burlington, Fanny Allen Hospital, Winooski, and the Porter Hospital, Middlebury; consulting gynecologist to the Mary Fletcher Hospital; aged 76; died, September 2, of diabetes mellitus, chronic myocarditis and hypertension.

**Ernest Coleman Levy**, Richmond, Va.; Medical College of Virginia, Richmond, 1890; professor of histology, pathology and bacteriology at his alma mater, 1897-1900, and in 1925 was professor of preventive medicine; health officer of Richmond, 1906-1917, and director of public welfare, 1919-1924; health officer of Tampa, Fla., 1925-1928; served during the World War; charter fellow and past president of the American Public Health Association; past president of the Richmond Academy of Medicine and Surgery; author of numerous papers on public health topics; aged 70; died, September 29.

**Julius C. Le Hardy** ☉ Major, U. S. Army, retired, Port St. Joe, Fla.; University of Georgia Medical Department, Augusta, 1893; veteran of the Spanish American and World wars; served as a reserve officer on active duty for many years; entered the medical corps of the regular army as a first lieutenant in 1927 and retired in the same year under a special act of Congress approved March 3, 1927, for disability in line of duty; in 1930 was retired as a major under act of June 21, 1930; aged 67; died, September 3, of a self-inflicted bullet wound.

**George Newton Bell**, West Hartford, Conn.; Yale University School of Medicine, New Haven, 1892; member of the Connecticut State Medical Society and the New England Surgical Society; fellow of the American College of Surgeons; consulting surgeon to the Hartford, Hartford Isolation and Mount Sinai hospitals, Hartford; Litchfield County Hospital, Winsted, Home for Crippled Children, Newington, Memorial Hospital, Manchester, Rockville City Hospital, Rockville, Bristol (Conn.) Hospital; aged 68; died, September 10, of cerebral hemorrhage.

**Russell Sturgis Rowland**, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901; member of the American Pediatric Society and the American Academy of Pediatrics; was awarded a silver medal for his excellent presentation of studies on lipid metabolism at the annual meeting of the American Medical Association in Detroit in 1930; on the staffs of the Children's, Harper and Woman's hospitals; aged 64; died, September 29, of cerebral thrombosis.

**Wesley Harold McKnight**, Bedford, Ind.; Indiana University School of Medicine, Indianapolis, 1922; member of the Indiana State Medical Association; past president and secretary of the Lawrence County Medical Society; served during the World War; on the staff of the Dunn Hospital; aged 42; died, September 9, in the Passavant Memorial Hospital, Chicago, of acute bacterial endocarditis.

**James Edward Neighbors** ☉ Poughkeepsie, N. Y.; Vanderbilt University School of Medicine, Nashville, Tenn., 1920; on the staffs of the Vassar Hospital and St. Francis Hospital, Poughkeepsie, Sharon (Conn.) Hospital, Butterfield Memorial Hospital, Cold Spring and St. Benedictine Hospital, Kingston; aged 40; died, September 13, in St. Luke's Hospital, New York.

**Edward Schnaper** ☉ New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; fellow of the American College of Surgeons; gynecologist to the Lebanon Hospital and consulting obstetrician to the New York Nursery and Child's Hospital; aged 63; died, September 3.

**Daniel Stevens Latham** ☉ Cranston, R. I.; Medical School of Maine, Portland, 1893; for many years health officer; at one time served in the house of representatives and later in the state senate; formerly a member of the school committee; aged 71; died, September 21, of coronary thrombosis.

**Robert Edwin Holmes**, Harrisburg, Pa.; Eclectic Medical Institute, Cincinnati, 1894; member of the Medical Society of the State of Pennsylvania; at one time member of the state

board of medical education and licensure; for many years on the staff of the Harrisburg Polyclinic; aged 78; died, September 6.

**Archie J. McDowell**, Soldiers Grove, Wis.; Milwaukee Medical College, 1898; member and past president of the State Medical Society of Wisconsin; formerly member of the state legislature; for many years president of the board of education; aged 74; died, August 28, of peritonitis and strangulated hernia.

**William Alexander Hackett**, Detroit; University of Toronto Faculty of Medicine, 1894; member of the Michigan State Medical Society; fellow of the American College of Surgeons; on the staff of St. Joseph's Mercy Hospital; aged 70; died, September 16, of carcinoma of the urinary bladder.

**Woodrow Charles Pickering**, Columbus, Ohio; Ohio Medical University, Columbus, 1901; member of the Ohio State Medical Association; for many years police and fire department physician; aged 64; died, September 22, in the Grant Hospital of acute monocytic leukemia.

**Guy Seward**, Fremont, Neb.; Barnes Medical College, St. Louis, 1902; member of the Nebraska State Medical Association; veteran of the Spanish-American and World wars; aged 64; died, September 6, in the Nicholas Senn Hospital, Omaha, of cerebral thrombosis.

**Worthington Seaton Russell** ☉ Woodbury Falls, N. Y.; University of the City of New York Medical Department, 1893; at one time an acting assistant surgeon with rank of lieutenant junior grade in the U. S. Navy; aged 68; died, August 16, of coronary occlusion.

**Louis Alden Pindler** ☉ Los Angeles; University and Bellevue Hospital Medical College, New York, 1920; on the staff of the White Memorial Hospital; aged 45; died, October 9, in the Lincoln Hospital of an infection resulting from a splinter in his hand.

**William Edward Gorman**, Springfield, Mass.; Atlantic Medical College, Baltimore, 1909; aged 69; on the staffs of the Mercy Hospital and the Wesson Hospital, where he died, September 9, of cerebral thrombosis, left hemiplegia and arteriosclerosis.

**Harold David Haney**, Western State Hospital, Tenn.; University of Tennessee College of Medicine, Memphis, 1934; member of the Tennessee State Medical Association; on the staff of the Western State Hospital; aged 29; died, September 13.

**Herman Walter MacDonald** ☉ Newcastle, Ind.; Indiana University School of Medicine, Indianapolis, 1909; on the staff of the Clinic Hospital; aged 55; died, September 21, in the Robert W. Long Hospital, Indianapolis, of peritonitis.

**Frank Willis Almond** ☉ Boise, Idaho; McGill University Faculty of Medicine, Montreal, Que., 1919; served with the Canadian Army during the World War; county health officer; aged 50; died, August 26, of coronary thrombosis.

**Edward Francis Brennan**, Norwood, Mass.; Tufts College Medical School, Boston, 1908; member of the Massachusetts Medical Society; formerly chairman of the school committee and board of health; aged 54; died, September 9.

**Butler Hall Sanchez**, Plant City, Fla.; Atlanta Medical College, 1914; member of the Florida Medical Association; served during the World War; aged 51; died, September 21 at St. Joseph's Hospital, Tampa, of pneumonia.

**Frank Alonzo Kirby** ☉ New Haven, Conn.; Columbian University Medical Department, Washington, D. C., 1895; aged 68; died, September 5, in Grace Hospital, of toxic purpura following transfusion and pernicious anemia.

**Walter C. Head**, Bessemer, Ala.; Birmingham Medical College, 1901; past president of the board of education; member of the Medical Association of the State of Alabama; aged 63; died, September 3, of carcinoma of the pancreas.

**David Wallace Mott**, Los Angeles; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1881; formerly member of the state senate; at one time mayor of Santa Paula, Calif.; aged 83; died, August 26.

**Albert Morton Shaw** ☉ Nauvoo, Ill.; Medical College of Ohio, Cincinnati, 1890; formerly secretary of the Hancock County Medical Society; aged 73; died, September 13, in Burlington, Iowa, of pyelonephritis.

**William D. Brydone-Jack**, Vancouver, B. C., Canada; L.R.C.P., L.R.C.S., Edinburgh, 1884; formerly coroner; for many years on the staff of the Vancouver General Hospital; aged 78; died, September 1.

**Rubert Stewart Royce**, Brooklyn; University of Vermont College of Medicine, Burlington, 1889; member of the Medical Society of the State of New York; aged 72; died, August 16, of angina pectoris.

**Francis W. McNamara**, Chicago; Chicago Medical College, 1889; for many years county jail physician; aged 71; died, September 16, in the Presbyterian Hospital of cerebral hemorrhage.

**Thomas Blanchard Herrick** Ⓢ Manson, Iowa; State University of Iowa College of Medicine, Iowa City, 1912; served during the World War; aged 52; died, September 2, of coronary thrombosis.

**Ernest Bonner**, Camden, Ala.; Bellevue Hospital Medical College, New York, 1898; member of the Medical Association of the State of Alabama; aged 63; died, September 19, of myocarditis.

**Leonard A. Muns**, Smithfield, N. C.; College of Physicians and Surgeons, Baltimore, 1885; aged 76; died, August 30, in the Johnston County Hospital of a fracture of the hip and pneumonia.

**Francis Paul Kean MacMurrough**, Jersey City, N. J.; St. Louis College of Physicians and Surgeons, 1886; served during the World War; aged 73; died, September 6, of heart disease.

**Edward Levis Prizer**, Southern Pines, N. C.; Harvard University Medical School, Boston, 1912; aged 53; died, September 7, of hypertrophic arthritis, chronic nephritis and uremia.

**Brown Lee Pursifull**, McKee, Ky.; St. Louis College of Physicians and Surgeons, 1920; aged 43; died, September 2, in the Veterans Administration Facility, Lexington, of pneumonia.

**Homer C. Behymer**, Amelia, Ohio; Eclectic Medical Institute, Cincinnati, 1895; aged 69; died, September 1, in St. Francis Hospital, Cincinnati, of arteriosclerosis and heart disease.

**Victor Josephson** Ⓢ Chicago; College of Physicians and Surgeons of Chicago, 1894; aged 70; died, September 11, of coronary thrombosis and arteriosclerotic heart disease.

**Perry Xavier Martin Jacobs**, Cincinnati; Cincinnati College of Medicine and Surgery, 1899; aged 66; died, September 12, of diabetes mellitus and cirrhosis of the liver.

**Robert H. Jacobs**, Joppa, Ill.; Kentucky School of Medicine, Louisville, 1894; served during the World War; aged 71; died, September 9, in Metropolis of paralysis agitans.

**Jane Orr**, Oakland, Calif.; Tufts College Medical School, Boston, 1901; member of the California Medical Association; aged 69; died, August 19, of coronary sclerosis.

**William Porter Moore**, College Grove, Tenn.; Vanderbilt University School of Medicine, Nashville, 1894; aged 65; died, September 1, of complications following typhoid.

**Harry Parke Beatty**, Chicago; University of Wisconsin Medical School, Madison, 1930; aged 33; died, September 4, of injuries received in an automobile accident.

**Albert Herman Lazere** Ⓢ Sioux City, Iowa; University of Illinois College of Medicine, Chicago, 1931; aged 35; died, September 8, of carcinoma of the stomach.

**Burton Willis Swayze**, Allentown, Pa.; Jefferson Medical College of Philadelphia, 1891; aged 70; died, August 1, in the Sacred Heart Hospital of carcinomatosis.

**Nathaniel Burwell**, Shepherdstown, W. Va.; University of Maryland School of Medicine, Baltimore, 1907; died, September 16, of pulmonary tuberculosis.

**Atchie M. Nicks**, St. Joe, Ark.; Memphis (Tenn.) Hospital Medical College, 1888; aged 75; died, August 28, of valvular heart disease and arthritis.

**Morris Leon Loevenson**, Chicago; College of Physicians and Surgeons, Baltimore, 1893; aged 76; died, September 27, of carcinoma of the stomach.

**Oliver Perry Erwin**, Medora, Ill.; Missouri Medical College, St. Louis, 1887; at one time mayor; aged 75; died, September 5, of cystitis.

**Augusta Nordell Carlson**, Boston; Boston University School of Medicine, 1914; aged 58; died, August 15, of diffuse cerebral sclerosis.

**Hugh Jenkins**, Tucson, Ariz.; Rush Medical College, Chicago, 1881; aged 81; died, September 19, of acute nephritis.

**Nelson Potter**, St. Louis; Barnes Medical College, St. Louis, 1905; aged 75; died, September 6, of uremia.

## Correspondence

### PRACTICAL MEDICAL ECONOMICS

*To the Editor:*—I have been able to make substantial financial progress in the past two years without increase in gross income and in spite of the business "recession" and even decrease in gross income during the past fourteen months, in a manner which could be used with profit and satisfaction by any harassed practitioner. There are few, if any, practitioners whose gross incomes would not allow them to live respectably and save money for old age if the practitioner did not make so many mistakes in management.

Record keeping is a great help. I got out the records of the people who had been guilty of gross nonpayment of obligations since 1925. The social and economic history of every one of these families and people was reviewed to see, principally, whether we had done a charitable act in serving them without being hard boiled about the pay. The result of the analysis was enlightening and profitable. Just about 5 per cent of these account losses were to people who could not pay at that time or any other and who deserved to be helped. The remaining 95 per cent were people whose protestation of poverty was a misrepresentation. They paid for their groceries, automobiles, gasoline, liquor, tobacco, vacations and everything else except their medical service. Location in a small community where one is able to know what the patients are doing when they are not ill, and how they live, has its analytic advantages. For the most part, the average individual's or family's claim that they cannot afford or pay for good medical service is not substantiated in fact. I have become so sensitized to the type and approach of the patient with the false claim of poverty that the first step of such an individual across the consultation room threshold and the first glance decide the credit problem, right there and then. Practitioners have for so many years been the dupes of every unscrupulous deadbeat, and still are, that a great many of the present (and threatening future) economic troubles of the profession arise from this. Having given so much so easily, the practitioner is now asked to give more.

Another fallacy is the inferiority complex-induced idea that it is necessary to "keep up with the Joneses." Most of the things that the Joneses do are an unmitigated bore and an offense to a moderately active intellect, besides, for the most part, being plain stupid. The entire family is much happier since we stopped purposely and energetically pursuing happiness at the bridge club, the golf course and over the social alcohol, and lived a more rational life. I have come to agree with a well known psychiatrist who expressed his conviction that the most of the wild pursuit of pleasure was but a fugue, an attempted flight from reality.

In another way I have saved money: I have gotten so that I can throw the average drug salesman, specialty salesman, instrument and gadget salesman out of the office without the least compunction whatever. Some of the salesmen were indignant, but I take notice that after these salesmen's day's work is done they go home or to their hotel and sit down and worry about their own troubles and not about mine, and why should I worry about theirs? This leads to the corollary that many practitioners have much too much of the wrong kind of equipment and many many too many pills, liquids, ointments and plasters, all of which cost them good money. Which also leads to the observation that it is not necessary to load the patient up with several kinds of medicine he does not need just to make him think you are doing something for him and to keep him satisfied. Many practitioners believe this semihumbog practice is necessary, but the conviction arises from the physi-

cian's lack of sufficient self respect and lack of confidence that his therapy is correct and the best available for the case at the time.

Another important way I have straightened out financial affairs comes under the head of "Trust no future, howe'er pleasant, let the dead past bury its dead, act, act in the living present, heart within and God o'erhead" (Longfellow), which, applied to medical practice, means Do not wait for future and perhaps never eventuating increased prosperity to plan your budget, savings and old age security. If increased income and prosperity come, fine, but in the meantime figure that life will be ever thus and plan accordingly. The average, well perhaps not the average but far too many, physicians are intending to plan their lives next week or next month or next year. Well, that time never comes, and they go on and on and on and on and know not where they are going. But I know where they are going. They are going where all unpractical fools deserve to go, physician or any one else. Do you remember Dickens's Micawber? When it was too late he philosophized: Income of five crown three shilling and expenditures of five crown five shilling, result misery; income of five crown three shilling and expenditures of five crown one shilling, result happiness.

GEORGE W. WILLIAMSON, M.D., Dundee, Mich.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### RESTORATION OF PATENCY OF OVIDUCTS

*To the Editor:*—A woman aged 30 is desirous of becoming pregnant. Pregnancy occurred at the age of 27 but was interrupted because of financial considerations she says, although I think there was some other reason. She has been advised as to the physiologic period and repeated efforts have been made. The tubes were recently tested for patency with air up to 200 mm. of mercury pressure and also with iodized oil and pictures were taken. The pictures reveal patency only to the fimbria with no leakage in the abdominal cavity. Is there a retrograde procedure whereby these tubes can be opened? Please give references to a description of this and your opinion on its results.

M.D., Florida.

**ANSWER.**—Transuterine inflation with air or gas, commonly known as the Rubin test, is the only nonoperative measure that might open the obstructed tubes. This procedure, primarily employed for diagnosis, results in reestablishing patency, followed by pregnancy in a modest percentage of cases.

Abdominal operative intervention has been looked on with greater favor during recent years, particularly in cases such as the one described.

### NO WAY TO INCREASE HEIGHT OF ADULT

*To the Editor:*—A man aged 29 is 5 feet 4 inches (163 cm.) tall and weighs 120 pounds (54 Kg.). He is in good health but comes every day to ask if it is possible for him to grow at least 5 inches more. I tell him it is impossible, but he insists, saying he read in an American paper about a pituitary gland extract and a certain class of exercises for increasing height. Is this possible?

A. JARAMILLO, M.D., Colombia, South America.

**ANSWER.**—In the present state of medical knowledge we know of nothing capable of adding 5 inches in stature to a patient 29 years of age. In all probability this patient's growth was completed from eight to ten years ago. Attempts at the present time at increasing height through the use of pituitary extract are more apt to lead to symptoms of acromegaly than to increased height. Perhaps the taking of a roentgenogram of the wrist and a demonstration that ossification has been completed, together with an explanation as to why no further growth is possible, would serve to satisfy the patient's mind. Once the epiphyses have joined the shaft of the long bone, growth is complete so far as height is concerned. Exercise likewise offers nothing; neither does a combination of exercise and endocrine products.

### EXTRACTS FROM FOODS FOR CUTANEOUS TESTS

*To the Editor:*—What is the best way to obtain dried protein extracts from foods for the cutaneous testing of allergic patients? Here in Mexico we have only those extracts prepared in the United States and since we have many foods unknown in that country, I am interested in obtaining the protein extracts from those foods.

LUIS PEREZ PARRA, M.D., Guadalajara, Mexico.

**ANSWER.**—The simplest method for obtaining atopens is that of extracting and drying the fresh food. Those foods which contain the juice require no solvent. The material is placed in a grinder or juicer. The juice obtained is filtered through filter paper and may then be dried either by passing a current of air over it or preferably under negative pressure in a vacuum desiccator containing sulfuric acid or some other dehydrating agent. In this group it is best to select ripe or nearly overripe fruits or vegetables, so that the pectin content may be at a minimum. Materials that contain little or no juice should be ground thoroughly and soaked in distilled water with frequent shakings for several days. During this period a small amount of toluene should be used as a preservative. The solution should then be dried as described.

Materials rich in fats require extraction with anhydrous ether after grinding and before aqueous extraction. This method, while simple, usually gives gummy material even after thorough drying. The nature of the substance, however, does not interfere with scratch tests.

Another method, which however requires considerable laboratory apparatus and training, consists of allowing the juice or extraction to fall, drop by drop, into acetone kept at minus 20 C. The final proportion of the material added to the acetone should not be more than one part of the material to nine parts of the acetone. The acetone is then filtered off and the precipitate is dried in a desiccator and then ground in a mortar. Solid carbon dioxide (dry ice) may be used in the acetone for keeping the temperature at minus 20 C. or below.

### DISCOVERY OF PHENOLPHTHALEIN AS LAXATIVE

*To the Editor:*—How and where was phenolphthalein discovered to have laxative properties? Is this dye ever used in the making of wine?

M.D., New Jersey.

**ANSWER.**—The laxative value of phenolphthalein was discovered by Zoltan von Vamossy, who published the paper announcing it in *Therapie der Gegenwart* 4:201 (May) 1902.

The story usually goes that the Hungarian government decided to use phenolphthalein for the denaturing of wine made from the husks of grapes. These artificial wines are made by adding sugar water to the pressed husks of grapes and allowing the mass to ferment. Soon after the law went into effect, it is said, a mysterious diarrheal disease overtook a large proportion of the poorer inhabitants of Hungary, which, it was discovered, was due to the denaturant, phenolphthalein. This story is disputed by Vamossy, who says that it is "unfair to the Hungarian government to think that it would have permitted anything to be added to any drink without previously investigating its effect on the health of the people."

Vamossy also says "That the laxative properties of this drug could not possibly have been discovered by the drinking of adulterated wines may be noted from the following: Phenolphthalein turns pink in an alkaline solution even in a dilution of one to ten millions, and as the amount of phenolphthalein that is needed to detect these wines is infinitesimal (0.1 Gm. to 100 liters), it would be necessary, even if 1 Gm. were used, to drink at least 10 liters of the wine before diarrhea would develop."

This, Vamossy says, is the true story of its discovery:

"When it was proposed to denature artificial wines with phenolphthalein, I was first entrusted with the task of investigating the harmlessness of this reagent. I carried on numerous experiments on animals with negative results. One small pet dog that received 6 Gm. of phenolphthalein became quite constipated and passed fecal masses as if it had been on a diet of bones, but these fecal masses became crimson on the addition of alkali. Following this the drug was tried on man. A colleague took 1 Gm. and I took 1.5 Gm. of phenolphthalein at 11 a. m. The effect appeared between 1 and 3 p. m. that afternoon, in the form of three to five watery evacuations accompanied by some borborygmi. A similar action occurred that evening and also the next morning but in no way disturbed us from our regular afternoon laboratory work or our night's rest. I became convinced that I had discovered a laxative of merit. It was easy to take owing to its tastelessness. It did not gripe and did not seem to have any drastic effect even in large doses (1.5 Gm.). It was later found that 0.1 Gm. taken in the evening emptied the contents of the colon the following morning, resulting in a copious but soft movement."

## VOMITING AND HIGH EXTERNAL TEMPERATURE

*To the Editor:*—A boy aged 10 years complains of itching, nausea and a sensation of heat during warm weather. These are followed in several days or weeks by vomiting. When he rides in a car to the hospital, 30 miles, the vomiting is stopped but he complains of being hot until he is given dextrose intravenously, which helps him. The attacks are not associated with fever, constipation or diarrhea. After the vomiting spells he has an enormous appetite for several weeks. As an infant he was given several formula diets and finally S M A and later Dryco. He could not take cow's milk until he was 2 years old and always had either constipation or diarrhea. When  $2\frac{1}{2}$  he had diphtheria and vomiting spells at intervals lasting between four and ten hours. At about 4 years of age he had vomiting and convulsions and intestinal infection during a spell of extremely hot weather ( $118^{\circ}$  F. for four days). During the subsequent two summers he was at the beach, where it was cool, and had several slight spells and continued to itch at intervals. When 6 years of age he had infantile paralysis and vomiting, from which he recovered without much paralysis but was left extremely nervous. In the summer of 1937, when 9 years old, he complained of a sensation of heat, itching and headache. He rode horseback in the mountains but had a vomiting spell, after which the appendix was removed. Five weeks later there was more vomiting and hemorrhage. He was given dextrose intravenously. In February 1938 he started vomiting blood, which was checked by dextrose intravenously. He had a similar attack May 21, 1938. The temperature where he lives is dry and hot, between 105 and 110. When taken out of this climate to the coast, where it is damp and cool, he has improved promptly. He gives a positive cutaneous test to casein, lactalbumin, orange, eggs, tomatoes, carrots, spinach, cabbage, corn, lima beans, bananas, beets, radishes, grapes, raisins, apricots, artichokes, chocolate, chicken and mustard. Any suggestions for diagnosis and treatment will be appreciated.

M.D., California.

**ANSWER.**—The heat-regulating mechanism of infants and children is more labile than that of adults. The symptoms enumerated in the history of this boy are rather vague but simulate the injurious effects of heat. The cutaneous eruption is probably also an effect of the high external temperature. As the patient was relieved by summering on the coast, it would seem that this is the most rational form of therapy for him.

## ETIOLOGY OF GLAUCOMA

*To the Editor:*—I have recently read an article entitled "The Symptomatology of Glaucoma and the Problem of Pathogenesis," by André Magitot, translated from the original articles in the *Annales d'oculistique* (166:356 [May], 439 [June], 565 [July], 609 [Aug.] 1929) by Hallard Beard. In some respects this article is so very different from sections on glaucoma in such books as Berens' and Gifford's recent textbooks for students that I am wondering whether the ideas presented in Magitot's article are commonly accepted by American ophthalmologists.

M.D., Nebraska.

**ANSWER.**—The series of articles by Magitot represents a somewhat individual point of view which is not shared in most of its essentials by the majority of ophthalmologists. His view represents a reaction from the older view that glaucoma is always due to an obstruction of the chamber angle. It is now admitted that a vascular factor plays a part in some cases, especially in acute glaucoma; but obstruction of the chamber angle is still considered an important factor. His view that chronic glaucoma should be treated by general measures is not accepted by most ophthalmologists, since the results of operations which secure more efficient filtration are known to be successful in the majority of cases. There is a great deal of other evidence that obstruction of the filtration angle cannot be neglected in glaucoma.

## CORNEAL ULCER FROM CATALIN?

*To the Editor:*—A patient has had a corneal ulcer. He was employed by a firm using catalin for plastic products and has been struck in the left eye on several occasions with catalin. Could this be a predisposing cause? What is the action of catalin on the cornea?

M.D., Massachusetts.

**ANSWER.**—Catalin is a synthetic resin, produced by the chemical combination of phenol and formaldehyde. It has the general appearance of honey and may be molded into suitable shapes to produce the desired manufactured objects. Solidification takes place as a result of curing, which is induced by heating. The completed objects are extremely hard and in some respects resemble bakelite, in others synthetic resin. Catalin products may be given a wide variety of colors as a result of the addition of aniline dyes. In some instances a rainbow or marbled effect may be desired, which may mean that several aniline dyes have to be utilized. Finished catalin products are apparently harmless, but in the manufacture of catalin numerous injuries have taken place, chiefly involving the eyes. In *Industrial Hygiene*, a publication of the Department of Labor of New York State (15, August 1936) there may be found an extensive discussion of the manufacture; use

and toxic properties of catalin. In the investigation there reported, it was noted that 55 per cent of the workers examined presented nondisabling conjunctivitis and 11 per cent an inflamed nasal mucosa and that more than 94 per cent presented some evidence of irritation of the upper respiratory tract. Industrial dermatitis was not detected. Workers examined complained that the entry of foreign bodies into their eyes was common and troublesome. Further, complaints were encountered as to eye discomfort, lacrimation and photophobia. However, these conditions were noted chiefly when workmen left the workpoint at the end of the day or at noontime, and particularly the eye complaints were more noticeable in colder weather.

In view of the fact that catalin is a known eye irritant, leading chiefly to low grade conjunctivitis, it is reasonable to believe that it might play some part in the occurrence of corneal ulcers. It may be believed that particles of larger sized dust entering the eye may have constituted a more direct factor in initiating the ulcer, which in turn may have been aggravated as a result of the irritant properties of the vapors of formaldehyde and phenol, if exposure to these was present.

## HAND INJURY

*To the Editor:*—Three months ago a woman aged 56 was struck on the dorsal surface of the right hand at the middle of the second metacarpal bone by a piece of glass falling from the seventh floor of a building. She received a small laceration and her hand was swollen for about three weeks. The wound healed by first intention and a small almost invisible scar remains. As a result of the injury the second and third fingers are much smaller than the corresponding fingers of the left hand; they are held slightly flexed and cannot be entirely straightened. Motion is decidedly limited, the patient being unable to close her hand completely. The skin over the fingers is tight and glistening. The fourth and fifth fingers also are involved but to a lesser extent. She complains of numbness over the dorsal surface of her second and third fingers. Her fingers are sensitive to cold. X-ray examination was negative at the time of the accident and a picture taken three weeks ago also was negative. What is the explanation of this change?

M.D., West Virginia.

**ANSWER.**—There was partial or complete division of the cutaneous branch of the radial nerve, of the common extensor tendons and possibly of the extensor indicis proprius. The scar tissue that formed helps to fix the injured tendons and to prevent complete extension and to restrict flexion. The same scar tissue interferes with the return flow of blood and return flow of lymph along the lymphatic channels and accounts for the poor circulation and sensitiveness to cold.

## EFFECT OF SKIN TUBERCULOSIS ON PULMONARY TUBERCULOSIS

*To the Editor:*—Does the presence of an associated cutaneous tuberculosis influence favorably the prognosis of pulmonary tuberculosis? Kindly list references on this subject.

M.D., New York.

**ANSWER.**—All observations and reports indicate that cutaneous tuberculosis rarely exists in fatal pulmonary tuberculosis but rather in conjunction with extrapulmonary disease. Wail (Inverse Relation Between Tuberculosis of the Skin and Tuberculosis of the Internal Organs, *Virchows Arch. f. path. Anat.* 277:115, 1930) and Memmesheimer (Influence of Cutaneous Tuberculosis on Pulmonary Tuberculosis, *Skin Clinic, Essen*, June 1936), among others, bear this out in their reports. It must not be assumed too hastily, however, that this is due to activity of the skin alone. While the skin seems to have a decided immunizing effect, the peculiarity of the bacilli that localize in the skin or other extrapulmonary organs must also be considered.

There are instances, however, in which bacilli of full virulence and typical behavior have appeared to yield to collateral skin infections. These effects cannot be explained satisfactorily on any other basis than as a result from stimulation of the skin.

Perhaps the most important report on this subject is that of Zinn and Katz (Biologische Einwirkung von der Haut auf den gesunden und tuberculösen Organismus, *Tuberculose-Bibliothek*, 1927, No. 27), who show that the skin is an organ subject to various stimuli and that definite immunizing properties originate in the skin as a result of chemical, bacterial or light stimuli. They cite the work of Petruschky, Moro, Ponnendorf and a host of others in which dead bacillary extracts were injected into the skin for immunization effects.

Kutschera (Therapy of Severe Pulmonary Tuberculosis by Artificial Production of Cutaneous Tuberculosis, *Wien. klin. Wchnschr.* 50:1547 [Nov. 12] 1937) has recently gone further and applied the principle in the use of living bacilli inoculated into the skin of tuberculous patients. Various protective anti-

bodies have been demonstrated after such inoculations. He recommends this procedure in various forms of slowly progressive secondary type of pulmonary tuberculosis, in which group he has made more than 1,000 inoculations without ill results. Primary tuberculosis inoculations, however, must scrupulously be avoided.

#### BLEPHAROCALASIS

*To the Editor:*—A white man aged 28 complains of a narrowing of his left palpebral fissure. He has been aware of this for at least three years. No pain and no disturbance of vision are associated and there are no headaches. In 1934 the left eye was edematous, mostly in the surrounding tissues. An eyeground examination then revealed a slight hyperemia, which appeared to follow the ingestion of strawberries. In forty-eight hours the edema subsided. In 1932 the patient suffered from a pansinusitis. Treatment consisted of irrigations of the left frontal sinus and both maxillary antrums. There was an uneventful recovery except for a postnasal discharge. At present examination reveals no inflammation of the lids or conjunctiva. The left upper eyelid is slightly edematous. Its edge covers the uppermost portion of the iris. There is a perceptible narrowing of the left palpebral fissure; there are no extra-ocular palsies and the eyegrounds are normal. Visual acuity of the left eye is 20/30 (Snellen), of the right eye 20/20. The serologic reaction is negative; neurologic examination and x-ray examination of all sinuses are negative. What are the possibilities? Will an angioneurotic edema last so long? In 1934 when the acute episode occurred, two ophthalmologists and two nose and throat men concurred in that diagnosis. I have noted several persons with a similar abnormality. The patient has shown me a photograph of himself at the age of 2. There is a suggestion of a slight narrowing of the left palpebral fissure. After loss of sleep the abnormality seems to be accentuated.

M.D., North Carolina.

*ANSWER:*—Apparently the case described is a condition known as blepharochalasis. This is usually the result of repeated attacks of acute edema of the lids resembling angioneurotic edema, but with a peculiarity of the connective tissue in the lid which leaves a thinned and pendulous upper lid. It is sometimes associated with vasomotor rhinitis during acute attacks. Efforts to trace it to some form of allergy have not been successful. It is necessary in many cases to resect a portion of skin in order to correct the overhanging portion of the lid. Shrinking of the nasal mucous membrane and the use of ice seem to help as much as anything.

#### PYELITIS AND FEVER

*To the Editor:*—Would diathermy be efficacious in the treatment of chronic pyelitis in a woman 30 years of age? The urine is usually negative for bacilli. I have been treating her with pyridium (0.2 Gm. daily taken before retiring). She has a fever every day of 99.6 F. between the hours of 11 a. m. and 4 p. m. only. Does the fever at these hours signify anything unusual?

M.D., New York.

*ANSWER:*—Diathermy is seldom of any value in the treatment of pyelitis. In the case mentioned it would seem important to submit this patient to a thorough urologic investigation in order to rule out the possibility of any obstruction in the urinary tract. If the examination is entirely negative, the use of mandelic acid or sulfanilamide should be highly efficacious in eradicating the existing infection. The occurrence of fever at the hours mentioned does not appear to have any significance.

#### FACIAL PALSY FROM TRAUMA

*To the Editor:*—A boy aged 8 fell from a tree 4 feet off the ground and hit his head; he did not lose consciousness and apparently was not hurt; from two to three days later he complained of soreness on the left side of his face and his mother noticed a paralysis on that side. I examined him one week after the fall; there were no symptoms of a fractured skull and x-ray examination shows none. A physical examination discloses a paralysis of the left side of the face; I did not test him with the faradic current. After four weeks there has been no change in his condition and I am interested in finding out whether anything can be done at present to restore function and when a plastic operation should be indicated if the condition fails to improve. I may add that the boy apparently was in perfect health before the accident and has been since it occurred.

M.D., Texas.

*ANSWER:*—The history suggests fracture of the skull which has injured the facial nerve or direct trauma to the nerve. The muscles of the face should be supported by an adhesive splint attached to the cheek and forehead. The boy should have massage and daily stimulation with the galvanic current as well as exercises in which he attempts to use that side of the face. If there is no return of function in the muscles of the face within three months, an anastomosis of the facial nerve and the hypoglossal and spinal accessory nerves should be considered. In the interim, the muscles of the face must be kept from relaxing and this is best accomplished by a splint.

#### DIVERTICULITIS OR CARCINOMA

*To the Editor:*—Can you outline for me or refer me to literature discussing the present status of diverticulitis and diverticulosis particularly with regard to its treatment? A white woman aged 61 came to me several months ago complaining of a loss of 40 pounds (18 Kg.) during the preceding eight months, accompanied by symptoms of weakness, anorexia, nausea and occasional vomiting. With the exception of a hemoglobin of 65 per cent, the blood and urine were normal. Physical examination was essentially negative. A gastrointestinal study disclosed an extensive diverticulitis. Treatment with a milk, cream and egg diet, barium sulfate powder orally and liquid petrolatum have been continued for about one month with little improvement in the anorexia and nausea, her most persistent and distressing symptoms. If she could achieve a normal food intake, her secondary symptoms would probably subside.

HOWARD G. BOSLAND, M.D., Verndale, Minn.

*ANSWER:*—The history as given suggests the probability of carcinoma. In about one third of the cases of diverticulosis complicated by sigmoiditis there is carcinoma, which is not revealed by an x-ray examination. Hence it may be wise to have surgical consultation. Diverticula of the colon are best handled with a low residue, high vitamin diet, and low olive oil retention enemas containing a small amount of aristol powder. Sufficient liquid petrolatum should be given by mouth to keep up the bowel movements.

#### GENTIAN VIOLET FOR ORAL LESIONS

*To the Editor:*—Of what value is gentian violet in lesions of the mouth, such as trench mouth? What is the best strength of solution to use for young children?

J. C. FRYE, M.D., Williamsburg, Pa.

*ANSWER:*—Gentian violet has been widely used in the treatment of various oral lesions but reports of its efficiency vary greatly. Aqueous solutions of gentian violet are nontoxic and nonirritating and yet can kill or inhibit the growth of many of the gram-positive bacteria of the mouth. Gentian violet is occasionally advocated for the treatment of Vincent's infection (trench mouth). Probably gentian violet would improve general oral hygiene as much as any other mild antiseptic and hence would have some beneficial effect on cases of Vincent's infection. However, oxidizing agents such as hydrogen peroxide and sodium perborate are usually more effective. Gentian violet is probably more valuable in the treatment of thrush and other fungous infections of the mouth. A 0.5 to 1 per cent aqueous solution of gentian violet may be used with safety on young children. A description of gentian violet and related rosaniline derivatives appears in New and Nonofficial Remedies, 1938, pages 218-221.

#### MACERATION OF FETUS

*To the Editor:*—What is the shortest time in which the skin of a dead fetus might become macerated? I delivered a stillborn infant at term with a tight knot in the cord. It was so macerated that the skin rubbed off on the slightest touch. Yet the mother thought she had felt life within twenty-four hours of the birth.

H. O. SKINNER, M.D., St. Paul.

*ANSWER:*—The skin of a dead fetus can macerate in a short time. It is entirely possible to have extensive maceration within a twenty-four hour period. Many factors influence the rate of maceration. Heat and infection are the most common of these factors. In the presence of one or both of these, marked maceration can occur within several hours.

#### LEGISLATION FOR DESTRUCTION OF RAGWEED

*To the Editor:*—In *Queries and Minor Notes* in *THE JOURNAL*, Oct. 8, 1938, page 1397, is a discussion of legislation concerning the destruction of ragweed. In this connection it is noteworthy that the sanitary code of the city of East Orange, N. J., received an additional amendment Oct. 5, 1933:

"That any thing, condition or act which is or may become a detriment or menace to human health and the following specific things, conditions and acts are, each and all of them, hereby declared to be and are defined as nuisances:

" . . . (g) Permitting ragweed in the flowering state to be or to grow upon any public or private property."

Health Officer.

F. J. OSBORNE, East Orange, N. J.

## Medical Examinations and Licensure

### COMING EXAMINATIONS

#### STATE AND TERRITORIAL BOARDS

**ALABAMA:** Montgomery, Jan. 3-5 and June 20-22. Sec., Dr. J. N. Baker, 517 Dexter Ave., Montgomery.

**ALASKA:** Juneau, March 2. Sec., Dr. W. W. Council, Box 561, Juneau.

**ARIZONA:** Basic Science. Tucson, Dec. 20. Sec., Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson.

**COLORADO:** Basic Science. Denver, Feb. 7-8. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver. Medical. Denver, Jan. 4-6. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

**CONNECTICUT:** Basic Science. New Haven, Feb. 11. Prerequisite to license examination. Address State Board of Healing Arts, 1895 Yale Station, New Haven.

**DELAWARE:** Dover, July 11-13. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

**DISTRICT OF COLUMBIA:** Basic Science. Washington, Dec. 26-27. Medical. Washington, Jan. 9-10. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

**GEORGIA:** Atlanta, June. Joint-Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.

**IDaho:** Boise, April 4-7. Dir., Bureau of Occupational License, Mr. D. B. Cruikshank, Rm. 355, State Capitol Bldg., Boise.

**ILLINOIS:** Chicago, Jan. 24-26. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

**INDIANA:** Indianapolis, June 20-22. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

**IOWA:** Medical. Des Moines, Dec. 1-3. Basic Science. Des Moines, Jan. 10. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.

**KANSAS:** Topeka, Dec. 13-14. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 North 7th St., Kansas City.

**KENTUCKY:** Louisville, Dec. 6-8. Sec., State Board of Health, Dr. A. T. McCormack, 620 S. Third St., Louisville.

**LOUISIANA:** New Orleans, Dec. 1-3. Sec., Dr. Roy B. Harrison, 1507 Hibernia Bank Bldg., New Orleans.

**MARYLAND:** Medical (Regular). Baltimore, Dec. 13-16. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. Medical (Homeopathic). Baltimore, Dec. 13-14. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

**MICHIGAN:** Ann Arbor and Detroit, June 14-16. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 100 W. Allegan St., Lansing.

**MINNESOTA:** Basic Science. Minneapolis, Jan. 3-4. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. Medical. Minneapolis, Jan. 17-19. Sec., Dr. Julian F. DuBois, 350 St. Peter St., St. Paul.

**MISSISSIPPI:** Reciprocity. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

**MONTANA:** Helena, April 4-5. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

**NEBRASKA:** Basic Science. Omaha, Jan. 10-11. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.

**NEW HAMPSHIRE:** Concord, March 9-10. Sec., Board of Registration in Medicine, Dr. Fred E. Clow, State House, Concord.

**NEW JERSEY:** Trenton, June 20-21. Address, Dr. William L. Wilbur, 28 W. State St., Trenton.

**NEW MEXICO:** Santa Fe, April. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

**NEW YORK:** Albany, Buffalo, New York and Syracuse, Jan. 23-26. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

**NORTH CAROLINA:** Reciprocity. Raleigh, December. Examination. Raleigh, June 19. Sec., Dr. William D. James, The Hamlet Hospital, Hamlet.

**NORTH DAKOTA:** Grand Forks, Jan. 3-6. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

**OHIO:** Columbus, Dec. 7-9. Sec., State Medical Board, Dr. H. M. Platter, 21 W. Broad St., Columbus.

**OKLAHOMA:** Basic Science. Oklahoma City, Nov. 30. Sec. of State, Hon. Frank C. Carter, State Capitol Bldg., Oklahoma City. Medical. Oklahoma City, Dec. 14. Sec., Dr. James D. Osborn Jr., Frederick.

**PENNSYLVANIA:** Philadelphia, Jan. 3-7. Sec., Board of Medical Education and Licensure, Dr. James A. Newpher, 400 Education Bldg., Harrisburg.

**PUERTO RICO:** San Juan, March 7. Sec., Dr. O. Costa Mandry, Department of Health, San Juan.

**SOUTH DAKOTA:** Pierre, Jan. 17-18. Director of Medical Licensure, Dr. B. A. Dyar, State Board of Health, Pierre.

**VERMONT:** Burlington, Feb. 14. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.

**VIRGINIA:** Richmond, Dec. 14-16. Sec., Dr. J. W. Preston, 30½ Franklin Road, Roanoke.

**WASHINGTON:** Basic Science. Seattle, Jan. 5-6. Medical. Seattle, Jan. 9-11. Dir., Department of Licenses, Mr. Harry C. Huse, Olympia.

**WISCONSIN:** Basic Science. Milwaukee, Dec. 3. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. Medical. Madison, Jan. 10-14. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

**WYOMING:** Cheyenne, Feb. 6. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

#### NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, Nov. 19, page 1955.

### Colorado October Endorsement Report

Dr. Harvey W. Snyder, secretary, Colorado State Board of Medical Examiners, reports twelve applicants licensed by endorsement at the meeting held in Denver, Oct. 4, 1938. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad. of
College of Medical Evangelists.....	(1924)	California,
(1933) Florida, (1938) N. B. M. Ex.		
Northwestern University Medical School.....	(1933)	Nebraska,
(1936) Illinois		

Rush Medical College.....	(1922)	(1927)	Illinois
State University of Iowa College of ..			Iowa
Johns Hopkins University School of ..			Utah
University of Minnesota Medical School.....	(1924)		Minnesota
Jefferson Medical College of Philadelphia.....	(1927)		New Jersey
Medical College of Virginia.....	(1937)		Virginia

### Iowa June Examination

Mr. H. W. Grefe, director, Division of Licensure and Registration, reports the written examination held at Iowa City, June 7-9, 1938. The examination covered eight subjects and included 100 questions. An average of 75 per cent was required to pass. Eighty-eight candidates were examined, of whom seventy-eight passed and ten failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Arkansas School of Medicine.....	(1937)	84.4	88.3
Rush Medical College .....	(1936)	79.9	(1937) 91.1
State University of Iowa College of Medicine.....	(1936)		86.4
(1938)* 78.8, 79.1, 80, 80.1, 80.5, 80.8, 81, 81.5, 81.9, 81.9, 81.9, 82, 82.4, 82.5, 82.5, 82.5, 82.9, 83, 83.1, 83.3, 83.4, 83.5, 83.8, 83.9, 83.9, 84.6, 84.6, 84.8, 84.9, 85.1, 85.1, 85.1, 85.4, 85.8, 86.1, 86.3, 86.3, 86.4, 86.5, 86.6, 86.6, 86.8, 86.8, 86.9, 86.9, 87, 87, 87, 87.1, 87.3, 87.4, 87.4, 87.5, 87.5, 87.6, 88, 88, 88.1, 88.3, 88.6, 88.6, 89, 89.3, 89.6, 90, 91, 91.1, 91.6, 92.5, 92.6			
University of Oregon Medical School.....	(1936)		88.1
Queen's University Faculty of Medicine.....	(1936)		83.8

School	FAILED	Year Grad.
State University of Iowa College of Medicine.....	(1938, 10)	

Thirty-three physicians were licensed by reciprocity and three physicians were licensed by endorsement from July 1 through Oct. 1, 1938. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Northwestern University Medical School.....	(1936)		California,
(1925), (1936), (1937) Illinois			
Rush Medical College .....	(1922)		Illinois
School of Medicine of the Division of Biological Sciences .....	(1934)		Illinois
University of Illinois College of Medicine (1931), (1936, 3), (1937), (1938, 2) Illinois			
Indiana University School of Medicine.....	(1929)		Indiana
University of Kansas School of Medicine.....	(1936, 2)		Kansas
University of Louisville School of Medicine.....	(1934)		Kentucky
University of Michigan Medical School.....	(1927)		Michigan
University of Minnesota Medical School.....	(1935, 2), (1937, 2)		Minnesota
Washington University School of ..	(1917)		Missouri
Creighton University School of ..			Nebraska
Univ. of Nebraska College of ..			Nebraska
Temple University School of Medicine.....	(1940)		New York
McGill University Faculty of Medicine.....	(1933)		Minnesota
Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin	(1933)		New York
Schlesische-Friedrich-Wilhelms-Universität Medizinische Fakultät, Breslau .....	(1934)		New York

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
College of Medical Evangelists.....	(1938) N. B. M. Ex.		
Harvard University Medical School.....	(1933) N. B. M. Ex.		
Temple University School of Medicine.....	(1935) N. B. M. Ex.		

\* Licenses withheld pending completion of internship.

### California Reciprocity and Endorsement Report

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports fifty-one physicians licensed by reciprocity and twelve physicians licensed by endorsement from May 11 through Sept. 29, 1938. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
George Washington University School of Medicine.....	(1936)		Illinois
University of Georgia School of Medicine.....	(1937)		Georgia
College of Physicians and Surgeons of Chicago.....	(1910)		Illinois
(1912) South Dakota			
Rush Medical College.....	(1912)		Illinois
University of Illinois College of Medicine.....	(1936)		Illinois
State University of Iowa College of Medicine.....	(1911)		Iowa,
(1930) Utah			
University of Kansas School of Medicine.....	(1935)		Kansas
University of Louisville School of Medicine.....	(1934)		Kentucky
University of Minnesota Medical School.....	(1925)		Minnesota
Harvard University School of Medicine.....	(1926)		Mass.
..	(1928), (1930)		Michigan
..	(1928)		Montana
..	(1928)		Idaho
..	(1928)		Missouri
..	(1928)		Oregon,
..	(1928)		
Creighton University School of Medicine.....	(1937)		Kansas
John A. Creighton Medical College .....	(1902)		Illinois
University of Nebraska College of Medicine.....	(1928)		Hawaii,
(1933) New York, (1908), (1917), (1932, 2), (1934, 2), (1937, 2) Nebraska			
Columbia Univ. College of Physicians and Surgeons.....	(1928)		New York

Eclectic Medical College of the City of New York....	(1901)	New York
New York University, University and Bellevue Hos- pital Medical College.....	(1917), (1928)	New York
University of Buffalo School of Medicine.....	(1900)	New York
University of Rochester School of Medicine.....	(1934)	New York
University of Cincinnati College of Medicine.....	(1938)	Ohio
Western Reserve University School of Med....	(1936), (1937)	Ohio
University of Oregon Medical School.....	(1936)	Oregon
Jefferson Medical College of Philadelphia.....	(1909)	Minnesota
(1924) Pennsylvania, (1934) Ohio		
University of Pennsylvania School of Medicine.....	(1924)	New York
Woman's Medical College of Pennsylvania.....	(1915)	New York
University of Vermont College of Medicine.....	(1923)	Vermont
University of Virginia Department of Medicine.....	(1932)	Virginia
University of St. Andrews Conjoint Medical School, Scotland .....	(1934)	New York

## Book Notices

**Experience in the Management of Fractures and Dislocations (Based on an Analysis of 4,390 Cases).** By the Staff of the Fracture Service, Massachusetts General Hospital, Boston. Under the General Editorship of Philip D. Wilson, M.D., Surgeon-in-Chief, Hospital for Ruptured and Crippled, New York. Cloth. Price, \$15. Pp. 1,036, with 1,419 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1938.

The staff of the Fracture Service of the Massachusetts General Hospital in Boston presents in this book a study of 3,985 patients who suffered 4,390 fractures and dislocations. Of this number they obtained end result examinations, a year or more after injury, in 1,192 cases. Their unusual presentation includes summaries of the history, examination, treatment and final examinations for each one of these end result cases, and also, for most of them, tracings of the early to late x-ray films. The twenty-three collaborators summarize the injuries in the various regions of the body. Following the introduction is the chapter on fractures and dislocations of the phalanges and metacarpals, which includes forty-five brief case histories outlining the associated injuries, treatment, complications and end results, and adjacent to this summary are sketches of the x-ray films in practically all the cases. Then follows the chapter on fractures and dislocations of the carpal bones by another member of the staff, with a brief introductory discussion of the anatomic considerations and a general consideration of the material studied. This chapter is concluded by summaries of twenty-six case histories, mostly accompanied by the pictures in each case. That is the general plan of presentation, which continues through the book. Chapter XVII is entitled "Fractures of the Facial Bones"; chapter XV, "Fractures and Dislocations of the Cervical Spine"; chapter XI, "Dislocation of the Shoulder Girdle"; chapter XIX, "Fractures of the Pelvis"; chapter XXII, "Ankle Fractures"; chapter XXXI, "Pathologic Fractures"; chapter XXXIII, "Delayed and Nonunion," and so on. The summaries of case reports are set in different type from the text. They begin with case report 1 in chapter II and end with case report 1396 in chapter XXXI.

This presentation differs from other treatises on fractures in that it is based on the actual study of cases and the analysis of the results of treatment. The authors have not gleaned all the information that may be obtained from analysis of these cases, and this large amount of source material is placed at the disposition of any student who cares to search further in the desire that every worthwhile conclusion may be drawn.

With the toll of injured victims ever increasing, physicians are confronted daily with problems on the correct solutions of which depend human lives. Conscious of such responsibility, practitioners are attending graduate fracture courses in ever increasing numbers.

The staff of the Fracture Service of the Massachusetts General Hospital for many years has conducted annually a graduate course on fractures. This book is the outgrowth of their teaching. The authors of the various chapters are those who

have taught in these courses in the field in which they were particularly competent. They are conscious of defects in this presentation, but the sincerity of their figures cannot be questioned. They have reported fully the unsatisfactory results along with the good results. Some of the bad results, however, were inevitable from the nature of the injury, and some of them were due to errors of judgment or mistakes in technic. The authors hope that this presentation may challenge others to present similarly their material. When a large body of facts representing results of treatment by all the different methods are available for study, progress will follow.

**A Handbook of Methods for the Study of Adolescent Children.** By William Walter Greulich, Ph.D., Harry G. Day, Sc.D., Sander E. Lachman, M.D., John B. Wolfe, Ph.D., and Frank K. Shuttleworth, Ph.D. Monographs of the Society for Research in Child Development, Volume III, No. 2 (Serial No. 15). Paper. Price, \$2.25. Pp. 406, with 30 illustrations and diagrams. Washington, D. C.: Society for Research in Child Development, National Research Council, 1938.

**The Adolescent Period: A Graphic and Pictorial Atlas.** By Frank K. Shuttleworth, Institute of Human Relations, Yale University, New Haven, Conn. Monographs of the Society for Research in Child Development, Volume III, No. 3 (Serial No. 16). Paper. Price, \$2. Pp. 246, with 458 illustrations and graphs. Washington, D. C.: Society for Research in Child Development, National Research Council, 1938.

The handbook and atlas have been prepared by a group of scientists who, over an appreciable period, have jointly reviewed critically and examined the literature on adolescence. Lawrence K. Frank, in an introduction, explains that the handbook is intended to be a methodological aid for students of child growth and development, particularly of the adolescent period. The several authors have covered the particular fields of their specialized interest. The material is organized in five parts, anatomic studies, biochemical and physiologic researches, medical and clinical aspects of adolescence, psychologic investigations, and a section on problems not involving direct measurements of children. The effort has been "to select from the literature those methods, technics and procedures which might be employed to record and, if possible, measure the growing child, in order to reveal the rate and direction of growth and development, or the developmental sequence, of the various structures, functions and activities that are being observed" (xv).

In the section on anthropometry, Dr. Greulich characterizes serial photography as the most valuable single technic for recording externally discernible bodily changes associated with growth and development. The general physical characteristics and changes associated with puberty are outlined extensively. The section on biochemical and physiologic aspects exhaustively covers the literature of the physiology of the skin, blood chemistry, respiration and energy metabolism, digestive organs, urine and feces. The extensive psychologic section comprehensively covers the literature on sensory and motor phenomena, intellectual and educational achievement and special abilities. The literature on sexual behavior is briefly and critically commented on to the effect that "but little in the way of established facts or well tried methods of obtaining facts" on adolescent sexual behavior is to be found. Much more exhaustive review of tests and observations of personal and social reactions is given. A final section presents literature on measurable aspects of the environment, discusses the logic of the approaches to the heredity-environment problem, and concludes with a discussion of statistical considerations.

The separate monograph, the atlas by Dr. Shuttleworth, consists of illustrations presenting data concerning adolescents and adolescent growth. They include graphs, charts, diagrams, photographs and all manner of data suitable for graphic or pictorial presentation. Material has been presented from the many aspects from which the adolescent is studied, physical growth and development, sexual maturation, health statistics, intellectual development, problems of behavior and occupational and sexual adjustments.

These two related works constitute a monumental achievement in selection and (in the handbook) of critical discussion of contributions from a vast and often confusing literature, which they now bring within relatively easy reach of the student or research worker. As a reference resource they amply justify the enormous labor they represent. As the authors have set out to do, they indicate what structures, functions and

activities of the growing child can and have been measured, and they aid the worker in making reliable measurements of his own.

Despite its bigness, the handbook omits the neurologic, psychiatric and endocrinologic literature of adolescence, which omission, the authors explain, is due to limitations of time and personnel. From the standpoint of the medical research worker in adolescence this is a disappointing omission, and the authors' hope that others will be inspired to make up for this lack will be shared by medical workers. One cannot lightly dismiss, however, the almost cursory manner in which some relatively subjective methods of studying behavior are dismissed in chapter XXI. These include observation, personal report (interviews, psychoanalysis, case study) as discussed in the chapter on sexual behavior. These methods should be critically regarded as methods of study of behavior in general, sexual or otherwise. The possibilities of these methods are sufficiently great that serious students of behavior should not content themselves with the easy evasion "as the procedure (psychoanalysis) now stands, however, it appears to be too subjective to be classified as a scientific approach." The authors make tentative suggestions as to the possible "scientific" utilization of these methods. They persist in the curious attitude that methods which gain information about the mental life of the disturbed individual might not be useful in gaining information about the normal adolescent. According to this logic, study of an individual suffering with an infection might not be expected to throw light on the maintaining of immunity from disease by the normal individual who shows no sign of infection. Not infrequently it requires the observation of individuals presenting exaggerated reaction to undue stress (whether physical or psychologic) to suggest the reactive potentialities and the laws governing these for the normal individual. Observation, whether of individuals in health or in disease, may lead to the clues necessary to set up properly controlled conditions for scientific investigation. (See D. M. Levy, *Studies in Sibling Rivalry*, American Orthopsychiatric Association, 1937, as an attempt in this direction.)

One would judge that after their experience in sifting such an immense literature the authors might be in a position to influence somewhat the direction of experimentation and observation that may tend toward a clearer conception of the adolescent, who still seems lost in the woods. If so, this may be reflected in the literature on adolescence of the next few years. Workers in the field of child development who will trouble to make proper use of these two publications will gain much profit for their pains.

*Some Account of the Pennsylvania Hospital from Its First Rise to the Beginning of the Year 1938.* By Francis R. Packard, M.D. Boards. Price, \$2.50. Pp. 133, with 44 illustrations. Philadelphia: Pennsylvania Hospital, 1938.

Firsts in various fields, whether books or buildings, are interesting. It is also important for American men of medicine to know something about the first hospital in the United States. This brief work by Packard, who is exceptionally well qualified as a medical historian, is full of important items. Benjamin Franklin while a member of the board of the Pennsylvania Hospital prepared and printed in his own printing plant a history of the hospital. To add to its historic value, "in the making of the present volume the printers have followed in general the size, format and typography of the earlier work." The Pennsylvania Hospital was founded in 1751. To quote from chapter II of Dr. Packard's work, "one of the objections made to the foundation of the hospital, when the matter was first brought up in the assembly, had been the expense that would be incurred in securing the services of physicians and surgeons for its staff. This was obviated when Drs. Lloyd Zachary, Thomas Bond and his brother, Phineas Bond, offered not only to serve the hospital for three years without compensation but also to supply all the medicines for that time at their own expense." What a fine commentary this is on the character of those men, and how timely it is to call attention to the fact that the medical profession at all times has served the best interests of humanity. The development of many departments and innovations is mentioned. Among these were the laboratory, first used as a place to

prepare drugs for the hospital. Then a sunstroke tent was erected, consisting of a large canvas pavilion, as a temporary but useful annex to the hospital, which served for some years and in which Dr. James J. Leveck introduced the so-called ice treatment for sunstroke. Although the Pennsylvania Hospital was founded largely by the Quakers and their influence, nevertheless it is "the only hospital in this country that has cared for sick or wounded soldiers in all the wars which have occurred on its soil." The staff of the hospital was a most distinguished one and the "high standard set by the original staff was well maintained in subsequent years." According to the author it was in the operating room of the Pennsylvania Hospital that the first thoracoplasty in a case of pulmonary tuberculosis was performed Nov. 13, 1911, by Dr. R. G. Le Conte. This brief work is embellished with a goodly number of interesting illustrations and presents at its close an iconography listing the various authorized engravings of the hospital. Dr. Packard's charming style makes this a delightful production from a literary standpoint. It is also most valuable as a historical document, one which lovers of medicine and those interested in its development in Philadelphia should read and thereby be both instructed and edified.

*Medicina legal y criminología afrocubanas.* Por Israel Castellanos, director del Gabinete nacional de Identificación de la República de Cuba. Paper. Pp. 152, with 26 illustrations. Havana: Molina y Cla, Impresores, 1937.

The study of medicolegal problems involved in medicine as practiced by the Cuban-African Negro witch doctor is of considerable sociologic interest and importance. The native physician sorcerers have, in their own circle, the right to kill as well as the right to cure. These sorcerers, called *ninigos* and *Brujos*, have often been referred to as criminals and yet in their social structure they are the omnipotent guardians of their race. Perhaps the most comprehensive study of the customs of these sorcerers is the book by Fernando Ortiz. The volume by Castellanos is not nearly as complete as the one by Ortiz but does give an insight into the medicolegal aspect of this problem, which is far from being solved.

*The Principles and Practice of Obstetrics.* By Joseph B. DeLee, A.M., M.D., Consultant in Obstetrics, Chicago Lying-in Hospital and Dispensary, Chicago. Seventh edition. Cloth. Price, \$12. Pp. 1,211, with 1,277 illustrations. Philadelphia & London: W. B. Saunders Company, 1938.

This book has now been before the profession for twenty-five years. It still reflects the teachings of the well known author at Northwestern University Medical School and at the University of Chicago. The obstetric technic described is the result of his experience of forty-four years in many hospitals, in a large maternity outdepartment, and in private and consulting practice in many homes. He has carefully worked over this new edition, adding much new material and omitting some obsolete material. The book remains virtually the same size as the preceding edition. Rapid developments in the physiology of menstruation and in the blood chemistry of the toxemias of pregnancy made necessary considerable revision of those sections in which work the author was assisted by Profs. M. E. Davis, W. J. Dieckmann and G. M. Dack of the University of Chicago. Dr. DeLee believes that lack of knowledge of the natural phenomena in labor is responsible for much of the present high maternal and fetal mortality. He has given therefore special attention to the mechanism of labor, incorporating the great contributions made by Caldwell, Moloy and D'Esopo, Rudolph and Ivy, and de Snoo. The chapter on obstetric anesthesia and analgesia has been enlarged. While nature intended labor to be a simple and harmless function, the softening influences of modern life, the author believes, have something to do with the present day suffering during childbirth. Nevertheless, the author has seen three painless labors and many others in which the pains were easily bearable, until at the very finish a few whiffs of ether completed a satisfactory delivery. The pain of labor, he believes, has been much exaggerated and attempts to get rid of all of it have been dangerous. In this chapter he discusses various anesthetics that have been used to relieve the pain of labor.

The chapter on contracted pelvis may seem long to those practitioners who do not make pelvic measurements or an antepartum study of the probable mechanism of labor. There is

much to learn about contracted pelvis and nature's method of overcoming mechanical difficulties. The developments in the endocrine or vitamin fields which appear to have been proved useful, the developments in internal medicine and surgery in their relation to pregnancy and tuberculosis, heart disease, diabetes and the anemias, have been incorporated as well as the treatment of puerperal sepsis by means of sulfanilamide and the new scalp traction forceps in placenta praevia. The author has kept the text representative of the obstetric thought of the day and his book remains preeminent in this field.

*Les méningo-neurobrucelloses.* Par Henri Roger et Yves Poursines. Paper. Price, 45 francs. Pp. 248. Paris: Masson & Cie, 1938.

Until recently, scant attention has been paid to the influence of brucellosis (undulant fever) on the central or peripheral nervous system. While scattered reports have appeared in American medical literature describing cases of meningitis or encephalitis due to *Brucella* infection, the attention of American physicians has not been directed particularly toward the frequency of those complications of brucellosis which affect the nervous system. Especially during the past decade, many reports have appeared in European literature, particularly in French journals, dealing with the neurobrucelloses. Roger and Poursines have brought together a combined account of their own researches and the published observations of other workers. The result is a masterly dissertation which deals concisely and clearly with an undoubtedly common, but infrequently recognized, phase of brucellosis. The predilection for meningeal localization, frequently associated with involvement of other parts of the nervous system, caused Roger and Poursines to select the descriptive name "meningoneurobrucellosis." The authors provide convincing evidence that the role of the meningitis predominates and that other nervous system involvement is usually secondary to the meningitis. Emphasis is placed on the long interval, often months or years, which may intervene between the acute phase of brucellosis and the delayed manifestations of neuromeningeal complications. The clinical manifestations vary greatly, depending on the extent of meningeal involvement and the presence of additional complications involving the brain, spinal cord or peripheral nerves. Not infrequently the symptoms simulate those of tuberculous meningitis, cerebrospinal syphilis or spinal cord tumor. The diagnostic, prognostic and therapeutic considerations are discussed in an adequate manner. This book should serve a useful purpose in stimulating physicians, particularly neurologists, to consider brucellosis as a not infrequent etiologic factor in many varieties of disease of the nervous system.

*The Rheumatic Diseases: A Course of Lectures Arranged by the Medical Staff of the St. John Clinic and Institute of Physical Medicine.* Edited by Sir Leonard Hill, M.B., LL.D., F.R.S., Director of Research, St. John Clinic and Institute of Physical Medicine, and Philip Ellman, M.D., M.R.C.P., Physician to St. John Clinic and Institute of Physical Medicine, London. With a foreword by Sir Arthur MacNalty, K.C.B., M.D., F.R.C.P., Chief Medical Officer to the Ministry of Health. Cloth. Price, \$4. Pp. 270, with 46 illustrations. Baltimore: William Wood & Company, 1938.

The editors of this book have assembled a course of lectures on rheumatic disease which had been given by members of the staff of the St. John Clinic and Institute of Physical Medicine and authorities from elsewhere during the winter and spring of 1936-1937. There are fifteen contributors and the result is a volume which, while lacking in integration and in the careful editing of some chapters, furnishes a number of thought provoking views. The chapter by R. Fortescue Fox is especially stimulating. His emphasis on the individual nature rather than the purely statistical position of the man of 35 or the young housewife with children faced with a life of progressive crippling deserves constant repetition. Furthermore, his discussion of the known incidence and economic cost of rheumatic disorders in several European countries throws into sharp contrast the almost complete lack of accurate information available in the United States. Fox's discussion also illustrates the greater extent of facilities for the care of chronic arthritis in some European countries, especially Sweden, which nearly twenty years ago erected three sanatoriums for physical, mental and occupational treatment. There is some difference of opinion expressed by the various authors, as was in fact intended, the "unitary theory" of rheumatic fever and rheumatoid arthritis

being supported by Sir William Wilcox and others, while Professor Leonard Findlay contends that the evidence in favor of the "unitary theory" is unconvincing. In the chapter by Koerner and Poulton, "Antistreptolysins and Blood Uric Acid in the Chronic Rheumatic Diseases," some original work is reported. Among other conclusions they found that the value of prontosil and prontosil album in rheumatoid arthritis is doubtful except perhaps in the more acute cases. Five chapters are devoted to problems of physical medicine in relation to rheumatic disease. The lecture by H. J. Taylor on the physical basis of physical medicine should serve as a worthwhile introduction to the subject especially for those whose memory of physics has faded. While there may be some difference of opinion with regard to the indications and effectiveness of the various types of physical therapy, these chapters are valuable in expressing the views of experienced workers.

*Aids to Histology.* By Alexander Goodall, M.D., F.R.C.P., Lecturer on Physiology, School of Medicine of the Royal Colleges, Edinburgh. Fourth edition. Cloth. Price, \$1.25. Pp. 151, with 26 illustrations. Baltimore: William Wood & Company, 1938.

This pocket-sized volume is an attempt to present the essential facts of histology in brief form. The author believes that the apparent complexity of histologic structure with the large number of technical terms bewilders the beginner and that a short guide may be of more service to junior students than lengthy descriptions. The book begins with a definition of histology, which word comes from *histos*, meaning a web. Brief discussions follow on the cell, mitosis and the ovum. Following is a five page chapter on epithelium. The next chapter takes up the connective tissues, the reticulo-endothelial system and the different kinds of cartilage. There is a three page chapter on muscle, and there are numerous brief chapters on various other systems. The nervous system is treated more fully. There are not many illustrations. This volume no doubt would aid in simplifying the extended discussions found in textbooks on histology. The book has gone into four editions since 1911.

*What's Wrong With Me?* By H. Ameroy Hartwell, M.D. Cloth. Price, \$1. Pp. 246. Weehawken, N. J.: The Author, 1938.

This book must be regarded as fundamentally unjustifiable and in violation of one of the most important established truths relating to health. It consists of a series of semitabular statements of symptoms, from which the patient is supposed to make his own tentative diagnosis, then go to a doctor for verification by the objective physical signs, and to seek the physician for treatment. The list of diseases dealt with starts with "abortion" and goes on through the alphabet to "yellow fever." It includes such serious conditions as acute appendicitis, acute Bright's disease and acute gastritis; these, incidentally, alphabetized under "acute." The book can be of little service to the layman and may result in raising needless alarms and contributing to the development of neuroses, unfounded fears, delay in correct diagnosis and treatment or hypochondriasis.

*Die Diffusionsanalyse am Blutplasmagel: Ein neuer Weg der Blutforschung.* Von Rudolf Bucher. Paper. Price, 30 Swiss francs. Pp. 123, with 70 illustrations. Basel: Benno Schwabe & Co., 1937.

This is a highly technical monograph describing original experiments applying the Liesegang ring phenomena to blood plasma. The author claims to have found certain specific differences in plasma from various species. He observed a characteristic pattern shift with age in all species, and certain changes in disease. These phenomena are apparently independent of total protein concentration. Their interpretation is obscure. The characteristic patterns are illustrated by excellent color plates.

*Materia Medica, Drug Administration and Prescription Writing.* By Oscar W. Bethea, M.D., Ph.G., Ph.M., Professor of Clinical Medicine, Tulane School of Medicine, New Orleans, La. Fifth edition. Cloth. Price, \$5. Pp. 577. Philadelphia: F. A. Davis Company, 1938.

In this book, which long ago established a place for itself, the reader finds a compendium of the drugs of the U. S. Pharmacopeia XI and the National Formulary VI, together with an excellent treatise on prescription writing. Not only are the drugs described but there are also historical sketches of many of the more important ones, and numerous prescriptions (properly credited to the standard works on therapeutics from

which they are drawn) are offered to illustrate the chief methods of their employment. The revision for the fifth edition has apparently been thorough and will certainly justify for the book a continued occupancy of one of the leading places in this textbook field.

**Attaining Manhood: A Doctor Talks to Boys About Sex.** By George W. Corner, M.D., Professor of Anatomy, the University of Rochester, Rochester, N. Y. Cloth. Price, \$1.25. Pp. 65, with 15 illustrations. New York & London: Harper & Brothers, 1938.

This is an excellent brief discussion of sex for adolescent boys. It avoids sensationalism and gives all the necessary information in condensed form. The diagrams of the sex organs of both the male and the female are exceptionally clear. The book is characterized by a strikingly unemotional style. Its brevity also commends it. The physician who seeks a book to recommend for growing boys, either his own or those of his patients, will make no mistake in choosing this one.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Workmen's Compensation Acts: Refusal to Undergo Third Operation for Hernia.**—Lindley, in the course of his employment, sustained an injury which resulted in double inguinal hernias. He submitted to two successive operations to correct the hernia on his left side but both operations proved unsuccessful. He then refused to submit either to a further operation to repair the condition on his left side or to an operation for the hernia on his right side. In proceedings instituted under the Oklahoma workmen's compensation act he was awarded compensation for permanent total disability and the employer appealed to the Supreme Court of Oklahoma.

Lindley's disability seemed to be due solely to his left inguinal hernia. The medical testimony on his behalf was to the effect that, because of his condition and the scar tissue which had formed as a result of the previous operations, further surgery was contraindicated and would be attended with more than usual danger and risk to health and life. While the employer's medical testimony tended to minimize the danger incident to a third operation, all the medical testimony was in substantial agreement that the presence of scar tissue would make the success of a further operation more problematic than it would otherwise be; that Lindley's disability would be permanent unless relieved by an operation; and that so long as the condition was unrelieved the performance of heavy manual labor would constitute a constant threat to health and life. While, said the court, no award can be made for permanent disability for hernia until the workman has submitted to an operation to correct the condition, a workman who has undergone such an operation and has received no relief therefrom is not thereafter required to submit to further operations on the chance that they may prove successful. This rule was announced in *United Service Street Car Co. v. McCarter*, 167 Okla. 433, 30 P. (2d) 456, in the following language:

An injured workman who is permanently and totally disabled by reason of a recurring hernia, and who has undergone one unsuccessful operation, is not required to subject himself to another operation which would be dangerous and probably useless, in order to minimize the financial burden imposed by law on his employer or his employer's insurance carrier.

The employer contended, furthermore, that Lindley had not sustained a permanent total disability as a result of the hernias, because the evidence showed that he actually performed work of substantially the same kind and character after his injury as he had performed prior thereto. With respect to this contention, Lindley testified that he had continued his work as a matter of necessity to provide for himself and for his wife and children. Ordinarily, said the Supreme Court, a disability cannot be classified as total under the workmen's compensation act where the earning power of the workman is not wholly destroyed and capacity to perform remunerative employment remains. Excluded from this rule, however, are those cases in which the

capacity of the workman is confined to the performance of work of a slight or trivial nature and those cases in which the capacity to do ordinary manual labor remains, as in the present case, but can be exercised only at the cost of serious discomfort and pain on the part of the workman. Sometimes men are impelled by stark necessity or a strong sense of duty and obligation to labor and to seek to carry on long after the human machine has been so broken and destroyed as to seem to make it impossible to drive it further. The wisdom of the effort and the struggle under such conditions may be questioned but the gallantry of the action should not be penalized. The evidence before the commission showed that Lindley had carried on under the urge of necessity and that in so doing he had risked both his health and his life and that the disability under which he was laboring would probably be permanent. Under such circumstances, said the Supreme Court, the commission was justified in finding that Lindley had sustained a permanent total disability as a result of his industrial injury. The court accordingly affirmed the award of compensation.—*Dierks Lumber & Coal Co. v. Lindley (Okla.)*, 77 P. (2d) 44.

**Workmen's Compensation Acts: Lead Poisoning as a Compensable Injury.**—Burden worked in an automobile assembly line near other workers who were grinding down rough spots on metal automobile bodies which had been treated with a lead compound. The air in this part of the plant was impregnated with lead dust and fine metal filings. On March 10, 1936, another worker, in using a compressed air hose, unexpectedly blew a cloud of lead dust into Burden's eyes, nose and mouth. About a week later he began to suffer from headaches, pains about his body, and cramps in his joints; his gums became tender and painful; urination was frequent and painful; and he suffered from nervousness and sleeplessness. As a result he was forced to quit work April 3, 1936. In May his condition was diagnosed as lead poisoning. He applied for and was granted compensation under the Texas workmen's compensation act and his employer's insurer filed an action in the appropriate federal district court to vacate the industrial board's award. From an adverse judgment by the district court, the insurer appealed to the United States circuit court of appeals, fifth circuit.

The insurer contended that Burden's condition was the result of an occupational disease and hence not compensable under the Texas act. Clearly, said the circuit court of appeals, Burden was disabled from lead poisoning. If this were solely the result of a gradual absorption of lead dust as a natural and ordinary hazard of his employment, it would not be compensable. There was evidence, however, of an unexpected, unintended and forcible blowing of an unusually large quantity of lead dust into Burden's face, nostrils and mouth about March 10, 1936, from which it may be found that he then accidentally inhaled an abnormal quantity. There was medical testimony to the effect that the gradual absorption of lead over a period of years would render a person less tolerant to lead than normally, and consequently more susceptible to a massive dose suddenly received; that "the amount of lead he had absorbed over the course of several years would be deposited into the bones and tissues, and probably would not have given any distress, unless he had a large dose to cause acute symptoms"; and that, if he had not had this lead in his system by this constant everyday absorption over four years of time, a massive dose would have caused a disability at the time anyway. The evidence was ample, in the opinion of the court, to support a finding of a compensable industrial injury.

The failure of Burden, in violation of a rule of employment, to wear a respirator which was provided for him and which presumably would have prevented his inhaling the lead dust did not defeat his claim for compensation, continued the court. When a workman is injured while doing something he is not employed to do—an act which is itself outside the scope of his employment—such injury is generally held not compensable because not suffered in the course of employment. Where, however, as here, the workman merely violates a rule relating only to the manner and method of doing his own work, such a violation does not defeat his right to compensation.

The award of compensation in favor of the workman was accordingly affirmed.—*Travelers Ins. Co. v. Burden*, 94 F. (2d) 880.

*Fifth Annual Meeting and Seventh Conference on Rheumatic Diseases, held in San Francisco, June 13, 1938*

LORING T. SWAIM, M.D., Boston, Secretary

(Continued from page 1962)

#### Immunologic and Bacteriologic Observations in Experimental Streptococcic Arthritis

DRS. D. MURRAY ANGEVINE, RUSSELL L. CECIL and SIDNEY ROTHBARD, New York: During a study of infectious arthritis in rabbits it was found that a small amount (from 0.1 to 2 cc.) of a broth culture of hemolytic streptococcus (AB 13) when injected intravenously produced arthritis in 87 per cent of fifty-four animals. The sedimentation rate was increased and streptococcic agglutinins were demonstrated in those animals which developed arthritis as well as in those which failed to do so. Cutaneous tests were done frequently, and only about 50 per cent of the rabbits developed sensitivity to streptococcus filtrate. Experiments were performed to determine whether there were any differences in the arthritis in normal and in immunized rabbits. Two groups of ten rabbits each received repeated injections of heat-killed organisms. One group was injected intradermally and the other intravenously. The intradermally immunized group became highly sensitive and the intravenously immunized group only slightly sensitive to intradermal injections of streptococcus filtrate. The immunized animals together with a group of normal rabbits were injected intravenously with 2 cc. of a broth culture of hemolytic streptococci. There were no conspicuous differences in the time of onset, the number of joints involved, the severity or the microscopic picture of the arthritis that developed in the three groups of animals. This experiment was repeated, but the rabbits were infected with multiple and varying doses. The first dose was 0.1 cc. of culture injected intravenously; ten days later 1 cc. was given and ten days after this 2 cc. Five of the nine intravenously immunized rabbits developed arthritis after the first infecting dose of 0.1 cc., whereas only one of eight intradermally immunized rabbits and two of eleven controls developed arthritis. Considerably less arthritis was found in this group at the time of necropsy than in the normal and intradermally immunized rabbits. This experiment indicates that although intravenous immunization caused a slight increase in susceptibility to arthritis there was also some protection against the development of arthritis.

#### DISCUSSION

DR. M. HENRY DAWSON, New York: These experiments clearly show that it is possible to produce a nonsuppurative arthritis in rabbits by the intravenous injection of small doses of hemolytic streptococci. The authors have shown that it is

possible to produce lesions which pathologically resemble closely those found in rheumatoid arthritis. However, the disease which they have experimentally produced differs in certain essential respects from the naturally occurring disease and no claims whatever are made that they have reproduced rheumatoid arthritis. There are two points in which the experimental disease differs from the naturally occurring one: In the experimental disease both the agglutinins and the sedimentation rate quickly return to normal. In rheumatoid arthritis the agglutinins persist throughout the disease and the sedimentation rate returns to normal only when the process becomes quiescent. Two other points are worthy of comment. The first is that normal rabbits, immune rabbits and hypersensitive rabbits were all found to respond in essentially the same manner. This is an important observation and should cause much concern to those who believe in allergic theories as well as those who believe in the value of vaccine therapy. The second point concerns the similarity in the agglutination results in the experimentally infected rabbits and in the natural disease rheumatoid arthritis. For many years I have been deeply interested in the capacity of rheumatoid arthritis serums to agglutinate hemolytic streptococci of group A. However, I have always been a little disturbed by the fact that this property is present in only about 70 per cent of cases. From the results reported today it would appear that agglutinins are similarly present in only 70 or 80 per cent of infected animals. It may well be that the failure of the remainder to respond may be associated with the feeble antigenic properties possessed by group A organisms.

DR. J. ALBERT KEY, St. Louis: I believe that in the beginning these streptococcic joints were purulent, but they are undoubtedly the nearest approach to experimental rheumatoid arthritis that I have seen. I have seen acute streptococcic joints in patients which quiet down and produce a chronic progressive arthritis. Usually, however, this is of a destructive character. In my experience, once the acute stage of the experimental infection was over there were no further involved joints. This is one of the distinguishing features between rheumatoid arthritis and experimental streptococcic arthritis. In my experimental arthritis I produce an acute arthritis in certain joints and there are no more joints involved. Clinically, unfortunately, that doesn't happen. The results of immunization were similar to my experience a few years ago. In a group of animals I tried to sensitize some and immunize others. I then injected small doses of streptococci directly into the joints. Streptococcus viridans and hemolytic streptococci were used and in all instances I was able to produce a purulent arthritis, regardless of whether or not the rabbits had been immunized or sensitized or were controls. In other words, I was not able to detect any difference between the three groups of animals. I have never accepted Ghormley and Allison's statement that there is a specific microscopic picture for atrophic arthritis. Joint tissues can react only in certain ways and if one submits the joint to a long drawn out chronic infection one gets proliferative changes and round cell infiltration and one may find these round cells in nodules with a relatively clear center. This microscopic picture can be produced in different ways and it is the result of chronic inflammation rather than of a specific type of infection.

DR. JAMES F. RINEHART, San Francisco: I am inclined to agree with Dr. Key that the experimental arthritis of Dr. Angevine and his co-workers may have been suppurative at the onset. At least it has not been clearly shown that this was not so. The chronic scorbutic arthritis in guinea pigs is distinctly a polyarthritis. If the deficiency is maintained over a period of time, various joints are involved in sequence. The knee joints usually are first affected and subsequently the wrists, the elbows and other joints. The arthritis is of a proliferative type. I would like to echo Dr. Key's remark about specificity of certain pathologic changes in rheumatoid arthritis. I do not believe that focal accumulations of lymphocytes in the subsynovial tissues can be considered specific for this type of arthritis. The subcutaneous nodule and comparable reactive changes in the periarticular tissues are probably much more nearly if not actually specific for this disease.

DR. D. MURRAY ANGEVINE, New York: When large doses of hemolytic streptococci are injected, the animals develop arthritis in practically every joint. In these cases the synovial fluid is usually purulent. However, if the dose is reduced so that the animal is not overwhelmed by the injection, an entirely different picture is seen in the joints. At first the process is an acute inflammatory one that is characterized by an increase in the number of polymorphonuclear leukocytes in the synovial fluid. However, this material is not frankly purulent and I do not believe that such a joint should be described as suppurative, although it would be regarded as an acute inflammatory exudate. When one does a necropsy on an animal with arthritis produced by a staphylococcus, one finds the same type of pus or purulent exudate in the joint space that one would find in a boil or carbuncle. This was not the case in the experimental streptococcal arthritis. The synovial fluid is easily aspirated, and we have done it repeatedly even as early as six hours after injection. We have found a considerable number of polymorphonuclear leukocytes in this aspirated fluid in the early stages. A rabbit's normal leukocyte count is about 10,000, or twice the normal for man. This might help to explain the larger number of polymorphonuclear leukocytes that are usually seen in this type of arthritis. It is well known that in rheumatoid arthritis the leukocyte count of the synovial fluid is often elevated to 25,000 and occasionally to 50,000 cells with a high percentage of polymorphonuclear leukocytes. We usually infer from this that the inflammatory process in the synovial fluid in cases of rheumatoid arthritis is often acute. If repeated injections of streptococci are given, one also produces a purulent arthritis. In reference to the question as to whether arthritis appeared in other joints after a longer time, I may say that we rarely observed joint involvement more than two weeks after injection. However, in a group of animals in which we have lowered the resistance by various means we have observed the development of arthritis in additional joints after an interval of thirty days subsequent to injection. I trust that we have not given the impression that we feel certain that there is an atypical pathologic picture for rheumatoid arthritis. We merely included this slide in order to demonstrate the type of disease process that we have attempted to reproduce.

#### The Treatment of Gonorrheal and Rheumatoid Arthritis with Sulfanilamide

DRS. HOWARD C. COGGESHALL and WALTER BAUER, Boston: In order to determine the value of sulfanilamide as a chemotherapeutic agent in the treatment of gonorrheal and rheumatoid arthritis, the following studies were undertaken:

1. Fourteen cases of proved and four cases of probable gonorrheal arthritis, two cases of uncomplicated gonorrhea, two cases of proved and two cases of probable gonorrheal prostatitis were carefully observed during and following the administration of large doses of sulfanilamide for periods of two weeks or longer.

2. The same large doses of sulfanilamide were administered for similar periods of time to ten patients suffering from mild to moderately severe rheumatoid arthritis of varying duration.

The dosage was calculated in the following manner: Three-fourths grain (0.15 Gm.) per pound (450 Gm.) of body weight was administered every twenty-four hours. In a few instances the initial dose equaled one-half the calculated twenty-four hour amount. This amount was readministered in four hours. Every four hours thereafter, the patient received one tenth of the calculated twenty-four hour amount. This method of administration results in sulfanilamide blood levels of 15 + mg. per hundred cubic centimeters. In most cases the initial dose and the dose administered every four hours, day and night, during the period of therapy equaled one sixth of the calculated twenty-four hour dose. This method of administration results in sulfanilamide blood levels of from 7 to 10 mg. per hundred cubic centimeters. Sulfanilamide when administered to persons with normal renal function is readily excreted. Therefore, if the necessary constant sulfanilamide blood levels are to be maintained throughout each twenty-four hour period, the drug must be administered every four hours day and night.

From the results obtained it would seem justifiable to conclude that sulfanilamide when administered in large doses for

two weeks or longer is a specific chemotherapeutic agent for certain strains of gonococci because: 1. Infected synovial fluids become sterile in from twenty-four to seventy-two hours after the institution of therapy. 2. In sixteen of the eighteen cases in which there was a proved genito-urinary focus, no gonococci were found after the third day of treatment. In one instance the genito-urinary focus did not become negative until the sulfanilamide blood level had reached 10 + mg. per hundred cubic centimeters. These seventeen patients remained clinically cured during the follow-up period. 3. The gonococcus complement fixation test failed to become positive in three cases of gonorrheal arthritis with infected synovial fluids. In nine of the remaining eighteen cases the complement fixation test became negative. 4. Nine of the proved and two of the probable cases of gonorrheal arthritis showed striking clinical improvement in from forty-eight to seventy-two hours after the institution of sulfanilamide therapy. The final end results in fourteen of the proved and four of the probable cases of gonorrheal arthritis were more satisfactory and took place in a shorter time than occurs with other forms of therapy. 5. The cases of gonorrheal arthritis in which an immediate clinical response occurred within forty-eight to seventy-two hours after the administration of sulfanilamide likewise showed a rapid fall in the erythrocyte sedimentation rate to normal.

Our results to date indicate that the dose of sulfanilamide necessary to cure gonococcal infections varies greatly. In some instances clinical cures are effected when the free sulfanilamide blood level is maintained at 5 mg. per hundred cubic centimeters while other cases require levels of 10 mg. or higher. The largest percentage of clinical cures will be obtained in patients with gonococcal infections if sulfanilamide is administered in large doses. If improvement does not occur within seventy-two hours, it probably means that the dosage employed is not adequate and therefore should be increased. Early administration of the drug in adequate amounts can prevent joint destruction.

The clinical course of rheumatoid arthritis was not affected in the ten patients treated with large doses of sulfanilamide, thus suggesting that the agent responsible for rheumatoid arthritis is not susceptible to this type of therapy. The rapid erythrocyte sedimentation rates observed in this group remained unchanged.

The toxic manifestations resulting from sulfanilamide therapy are readily recognized. The majority of them do not represent serious complications. Cyanosis is always present in patients receiving large doses. The dyspnea and the reduction of the plasma carbon dioxide content is directly related to alterations in the electrolyte metabolism (unpublished data). We have not encountered acute hemolytic anemia during the administration of sulfanilamide but have observed a slow, progressive subclinical hemolytic anemia in twelve cases. Leukopenia was observed in two cases.

#### DISCUSSION

DR. T. DUCKETT JONES, Boston: The excellent results of Drs. Bauer and Coggeshall in treating gonorrheal arthritis are in no sense approached in rheumatic fever. We cannot even conclude that the clinical course is unaltered, as they do with regard to sulfanilamide in the treatment of rheumatoid arthritis. I had high hopes when the drug was first introduced that it might be effective either in the prevention or in the treatment of rheumatic fever. No encouragement has been reported to date for either. Swift has reported its ineffectiveness in eight cases and was led to conclude that the toxic action of the drug in active rheumatic fever far outweighs the beneficial therapeutic effect. In fact, from his protocols it is difficult to see that any ameliorating influence was noted. I have noted no definite beneficial effect on the course of rheumatic fever although I have tried it in fifty-eight cases in which varying degrees of severity of the disease occurred. Striking is the fact that thirty-one of the fifty-eight patients presented definite evidence of toxicity to the drug. The more severe the rheumatic fever, the more frequent and severe the reaction. It is dangerous in the seriously ill rheumatic fever subject, and I should strongly urge against its administration. I have encountered pulmonary edema in such patients. Because of

the frequency of the association of hemolytic streptococcus infection in conjunction with the onset and recurrence of rheumatic fever, it was at first thought that studies of etiologic significance might be obtained; but this hope was dispelled by Swift. He demonstrated, and I have confirmed the observation, that hemolytic streptococcus immune responses, as indicated by a rise in the antistreptolysin titer, occur in rheumatic fever subjects despite the use of sulfanilamide. A small group of rheumatic fever subjects having hemolytic streptococcus throat infections were treated with sulfanilamide in an attempt to prevent the development of recurrent rheumatic fever. Alternate patients were given salicylates as a control group. In each group (six each) there were two severe recurrences and a fatal issue in each. The only difference between the two groups was the evident comfort of the group treated with acetylsalicylic acid as compared to the patients receiving sulfanilamide. This does not completely settle the question of prevention of recurrences of rheumatic fever and I am sure that some one will ultimately present a study large enough to be of statistical value, in which the blood level of free sulfanilamide in rheumatic fever subjects is kept at a reasonably high level during the winter and spring seasons when hemolytic streptococcus infection and recurrent rheumatic fever are common. I should like to stress with the authors that large doses be given and spaced throughout the day, that the blood level of free sulfanilamide be frequently determined and kept at least near the 10 mg. mark, and that complete blood studies be made at frequent intervals. Only when these features are observed will it be possible to compare reports on the therapeutic value of sulfanilamide.

DR. M. HENRY DAWSON, New York: Since March 1937 I have treated thirty-two patients suffering from gonorrheal arthritis with sulfanilamide. The results, while favorable, have not been as brilliantly successful as those reported by Drs. Coggeshall and Bauer, but I think from their report that some of the reasons are apparent. In the first place, I have treated a large number of chronic and subacute cases and in some of these the results have been equivocal. In many of the acute cases I have had the same spectacular success which has been reported. In the second place, my patients for the most part have been treated in an ambulatory clinic where it has not been possible to give as large doses of the drug; indeed, the whole problem of dosage could not be controlled. There are now a large number of favorable reports in the literature concerning the value of sulfanilamide in gonococcal infections and the carefully controlled work reported by Drs. Coggeshall and Bauer is particularly conclusive. I should like to add a few words concerning a procedure which I have recently tried on resistant and subacute and chronic cases; that is, a combination of sulfanilamide and fever therapy. The procedure has been to employ more moderate degrees of fever than those customarily employed in treating this disease, usually from 104 to 105 F. for five or six hours together with sulfanilamide (1.2 Gm. every six hours). The results of this combined treatment have been almost uniformly successful and several cases which did not respond to the drug alone were quickly cured. Similar results have been reported by Ballinger, Elder and McDonald and by Cheetham and Roemer. The results obtained by Drs. Coggeshall and Bauer with the use of sulfanilamide alone have been so good that it may not be necessary to use combined therapy. In any case it would appear that we now possess highly effective methods for the treatment of this condition.

DR. PHILIP S. HENCH, Rochester, Minn.: In the past eight years great advances have been made in the treatment of gonorrheal arthritis. Although I certainly do not begrudge the victims of the disease their good fortune in now having at hand such successful measures for treatment, it has always seemed to me rather "unfair" that that much larger army, the poor victims of atrophic arthritis, must still wait for an equally rapid and successful treatment. At the moment some physicians are arguing the respective merits of fever therapy and sulfanilamide for gonorrhea and gonorrheal arthritis. But the argument will not long continue because any patient would rather take pills, even though they produce certain disagreeable symptoms, than endure the stress of prolonged sessions of fever therapy. Furthermore, current experiences indicate that, in general,

sulfanilamide is as promptly successful as is fever therapy. However, a small percentage of patients with gonorrhea and gonorrheal arthritis do not respond to the administration of sulfanilamide or cannot take it in effective amounts because of its toxicity for them. In my experience about 10 per cent of patients with gonorrhea either cannot tolerate sulfanilamide at all or cannot tolerate enough of it to be effective. When a patient with gonorrheal arthritis does not respond promptly after taking sulfanilamide for three or four days, we at the Mayo Clinic discontinue the drug at once and prescribe fever therapy without further delay in order to avoid the risk of serious articular destruction. Sometimes fever therapy is then promptly successful. There are certain particularly potent strains of gonococci that are resistant not only to sulfanilamide but also to fever. Against such strains the use of sulfanilamide combined with fever therapy is at times effective; sometimes it is not. At the Mayo Clinic we have been using, in general, about two-thirds the amount of sulfanilamide advocated by Drs. Coggeshall and Bauer; perhaps our doses were inadequate in some cases. However, Dr. Cook of our urologic department has generally found that patients who did not respond to a daily dose of from 60 to 80 grains (4 to 5.3 Gm.) of sulfanilamide usually failed to respond also when the dose was increased to 100 or 120 grains (6.5 to 8 Gm.) daily. We have been disappointed with the results of sulfanilamide in the treatment of atrophic arthritis and rheumatic fever. In such conditions the patients have not been significantly benefited and marked toxicity frequently has developed. In almost the first case of atrophic arthritis in which we used this treatment a serious agranulocytosis developed but the patient fortunately recovered; this was the first instance of this kind brought to the attention of the American dispensers of the drug. In another case of atrophic arthritis, chills and fever (to 105 F.) occurred for four days; these symptoms subsided promptly when the administration of sulfanilamide was stopped. In still another case of atrophic arthritis fever (102 F.) occurred daily, associated with prostration and anorexia; although the administration of the drug was promptly stopped, these symptoms persisted for about three weeks. Although these poor results from sulfanilamide do not entirely contradict the hemolytic streptococcus theories of atrophic arthritis and of rheumatic fever, they do put the adherents of these theories on the defensive and I should like to hear some discussion on this point.

#### Neuropathic Joint Disease

DRS. KEENE O. HALDEMAN and RALPH SOTO-HALL, San Francisco: Certain diseases and injuries involving the spinal cord destroy the sensory protective mechanism of joints. Such joints, with single or repeated traumas, develop effusion and ligamentous relaxation, which is followed by the erosion of their cartilage, an irregular sclerosis of the subchondral bone, the production of parosteal bone, and intra-articular fractures which lead to a more or less complete disintegration of the joint. The absence of pain and the clinical and laboratory evidence of tabes dorsalis, syringomyelia or other cord lesions complete the picture of a neuroarthropathy, or so-called Charcot joint.

A series of forty-six patients showing neuropathic joint involvements in tabes dorsalis, syringomyelia, leprosy and traumatic paraplegia have been studied. The records of the forty patients suffering from tabetic arthropathies were tabulated according to the age, sex and joint involvement and certain clinical and laboratory observations. The proportion of males to females with such arthropathies is similar to the sex incidence of tabes dorsalis. The great majority of joint involvements appear between the ages of 40 and 60 years, at an average of twenty years after the occurrence of the primary lesion of syphilis.

Charcot joints most frequently occur in the lower extremity, the knee joint being the usual site of involvement. The positive clinical evidence of rigid pupils and absent knee jerks is of much greater importance than the various tests performed on the blood and spinal fluid in the diagnosis of a tabetic arthropathy. In an early stage of the neuropathic joint disease, its progress may be halted by the use of a protective brace.

We have adopted a method of producing the fusion of a Charcot joint in two stages. A preliminary drilling of the ends of the bones making up the joint is done for the purpose of

increasing their osteogenic power, followed in six weeks by the usual arthrodesing operation. Such a procedure in five cases resulted in firm bony fusion in three instances, with the final result not yet determined in the remaining two.

#### DISCUSSION

DR. L. MAXWELL LOCKIE, Buffalo: It is surprising that so many of these patients show a multiplicity of the joint involvement of the Charcot type. Many physicians erroneously dismiss the diagnosis of syphilitic joint disease if the blood Wassermann reaction is negative.

DR. ROBERT WARTENBERG, San Francisco: This study reminds us that there is such a definite clinical entity as the tabetic neuropathic joint, and that it is not, as Virchow believed, simply a modified arthritis deformans occurring in a tabetic patient. There are three theories of pathogenesis. The first considers the tabetic joint as due to an avascular, inflammatory process, from a syphilitic arteritis, phlebitis and osteitis. This theory can be easily disproved. The clinical picture of the two diseases is quite different. The "mechanical" theory states that the tabetic joints are essentially traumatic in origin and due to a combination of analgesia, hypotonia, loose joints, osteoporosis and ataxia. The tabetic patient maltreats his joints and doesn't feel it. Generally speaking, it is inconceivable that the normal use of the limbs and the spine could produce, even if the sensibility is lost, such grotesque bone proliferation and bone destruction as are found in tabetic joints. There is no adequate relationship between cause and effect. It is a clinical fact that tabetic joints may be demonstrable, especially by x-ray examination, at an early period of the tabes when there is no ataxia and no analgesia. They may develop in bedridden patients and appear often acutely. Sometimes the analgesia is not complete and yet the joint changes are profound. This theory cannot explain the "mal perforans" which often accompanies the tabetic joint or the arthropathies in syringomyelia where there is no ataxia. To support the mechanical theory, experimental work on cats has been done: the posterior roots have been cut, the limbs rendered anesthetic and traumatized. Arthropathies similar to those of the tabetic were claimed to be thus produced. But in addition to the sensory fibers which were cut in these experiments, they have in all probability also to do with transmission of trophic impulses. The third, the trophic, theory considers as the fundamental pathogenic factor in the production of tabetic joints the disturbance in the nervous trophic regulation. Although the trophic state of the tissues is essentially the function of the tissue cells themselves and there are in all probability no specific trophic fibers, a trophic regulatory influence of the nervous system must be assumed. The trophic impulses avail themselves of other tracts, such as motor, vasomotor, secretory and sensory fibers which are capable of antidromic conduction. Certain manifestations in tabes point to their possible sympathetic origin: subcutaneous and intestinal hemorrhages, visceral pain attacks, secretory crises, i. e. gastrorrhea, sialorrhea, galactorrhea. Interesting in this regard are the recently discovered local disturbances in sympathetic vessel innervation found in unilateral tabetic arthropathies, especially in the neighborhood of the affected joints. The following pathologic disturbances were found: elevation of the local temperature, rise in the arterial and venous blood pressure, increase of the oscillometric index, anomalies of the sweat secretion and disturbances in the pilomotor reflex. These clinical observations, together with the postmortem changes, indicate the role of the sympathetic nervous system in this disease and possibly also in the production of tabetic joints. The trophic influence is exerted by a reflex arc in the same way as is the motor influence. The centripetal limb of this arc probably goes through the sensory fibers, the centrifugal through the vasomotor fibers. The lesion which produces trophic disturbances may lie at any point of these two limbs or at their juncture. It is essential for the understanding of pathologic trophic changes to bear in mind that the trophic state of the tissues is much more influenced by a pathologic change of this nervous regulation than by a complete cessation. The cardinal sign of tabes, ataxia, is due to the fact that the outgoing motor impulses are not properly regulated by the incoming sensory impulses. In tabes the nervous trophic regulation is disturbed in the same way as the motor mechanism. In both instances the reflex arc is disturbed, and in both instances there is too much or too little innervation.

In the tabetic joints, both grotesque bone proliferation and bone destruction occur. By this trophic-ataxia theory the pronounced influence of ataxia and trauma can be easily explained. Asher, has demonstrated that a skin with disturbed sympathetic innervation shows diminished resistance. In the same way the trophic regulation of tabetic joints thus far maintained fails when ataxia, loose joints and so on put too severe requirements on the joints. The whole problem is still not solved and the words of Virchow in 1854 "The trophic influence of the nerves is still a dark chapter" even now hold true.

DR. J. ALBERT KEY, St. Louis: What happens in Charcot joints is not due to trauma and is not due to a change in the blood vessels. There is a decrease in the toughness of the tissue; this change is not limited to the bone and cartilage. The ligaments disintegrate. This is not due to the loss of muscle tone. Persons who walk year after year with infantile paralysis develop deformities; the weak muscles stretch and their ligaments are put to tremendous abnormal strains. Their articular surfaces are subjected to mechanical insults far greater than occur in Charcot joints, yet the articular surfaces remain in good condition. So I am perfectly sure in my own mind that in Charcot joints there is a trophic change and that that change affects the white fibrous tissue—not only the white fibrous tissues of the ligaments but the cartilage and the bone. The bone loses its toughness and disintegrates, and so does the cartilage. It is obvious that tabetic patients don't have any difficulty in producing bone. I have always thought that the reason Charcot joints were considered difficult to operate on and fuse was that the patients are difficult to treat. The muscles have lost their tone, there is nothing to hold these bone ends together, and mechanical fixation is necessary. Some years ago I published a paper in which I advised putting a pin through the tibia, another through the femur and pulling them together with turnbuckles and that worked all right. Bone is more apt to unite if one bores holes in it in an attempt to convert the hard compact bone to a soft, spongy cancellous bone, because new channels for bone to grow are opened. I think this method of Drs. Haldeman and Soto-Hall of doing it in two stages is a good one.

DR. H. H. MANN, Los Angeles: How would you diagnose a case of tabes in which the symptoms are in the hip joint, and the x-ray examination shows a reduction in joint space? As rheumatoid arthritis, tuberculosis, or Charcot joint? Would the sedimentation rate be of any value?

DR. C. L. STEINBERG, Rochester, N. Y.: For several years I have observed a neuropathic syndrome associated with atrophic or rheumatoid arthritis. This syndrome is characterized by catarrhal involvement of the cochlear division of the acoustic nerve. The vestibular root escapes injury. The "nerve" deafness is associated with exacerbations of the arthritis. These people become quite deaf during exacerbations and have normal or almost normal hearing with remissions or "cure" of the arthritis. This syndrome has been observed not infrequently in the third and fourth decades. The improved hearing noted in this group might be due to the remission or it might occur from the large doses of vitamin B<sub>1</sub> that I have been employing in their treatment. For the past two years I have been giving my arthritic patients a minimum of 400 B<sub>1</sub> units daily for its possible analgesic action. The analgesia has not occurred but auditory improvement has been noted. Drummond in 1934, Selfridge in 1937 and several other otologists have described some types of eighth nerve deafness that responded to vitamin B<sub>1</sub>. Selfridge has apparently been able to produce a progressive degeneration of the eighth nerve in animals fed a deficient vitamin B<sub>1</sub> diet. May not the increased demand for vitamin B previously suggested in a recently published article account for the eighth nerve involvement in arthritis?

DR. KEENE O. HALDEMAN, San Francisco: We believe that the differential diagnosis in involvement of the hip rests primarily on the absence of pain and on the proliferative changes which one occasionally sees. Most of our cases of Charcot hip had a fracture and then went on to a disintegration of the hip. In our entire series of forty tabetic arthropathies, eighteen patients gave a history of fractures, which often seemed to initiate the changes in the involved joint.

(To be continued)

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

\*Phagocytic Activity of Human Leukocytes, with Special Reference to Their Type and Maturity. A. J. Hertzog, Minneapolis.—p. 595.

Lymph Node Metastasis of Sarcoma. S. Warren and R. W. Meyer, Boston.—p. 605.

Primary Liposarcoma of Bone: Report of Case. J. Duffy and F. W. Stewart, New York.—p. 621.

**Infectious Agent of Inclusion Blennorrhoea.**—In trying to prove that inclusion blennorrhoea and trachoma are separate entities, Julianelle and his associates studied the twenty-two cases of inclusion blennorrhoea admitted to the ophthalmologic clinic of Washington University, the St. Louis Maternity Hospital (three) and the Bethesda Hospital of St. Louis (one). Diagnosis was verified by a search for the characteristic inclusions. Material for study consisted of a suspension of tissue fragments obtained by scraping (for therapeutic purposes) the conjunctiva of the everted lid. The tissues thus removed were emulsified in 1 cc. of veal infusion broth ( $p_H$  7.6 to 7.8). The suspension of tissues was always triturated under sterile conditions, without the intervention of abrasive substances, immediately on return to the laboratory. In testing the infectivity of the tissues, inoculations were made by direct swabbing from patient to animal (apes and monkeys), by swabbing with the suspension of tissues or by injection. A corollary experiment was conducted in which animals recovering from experimental inclusion blennorrhoea were inoculated at a later date with active material from trachoma. It was not possible to show that the former infection offered any protection to the later inoculation. The studies suggest that the infectious agent of inclusion blennorrhoea is not bacterial. It appears to be a virus capable of inducing specific infection in monkeys after passage through Berkefeld V and collodion filters, in this respect corroborating and amplifying experiments of other observers. Analysis of the individual manifestations reveals that both in spontaneous and in experimental infection there is a shortening of the incubation period and duration in inclusion blennorrhoea. While in appearance the two diseases are similar in the monkey, in man trachoma only induces cicatrization, corneal complications and impairment of visual acuity and exhibits a marked tendency toward recurrence after apparent healing. Silver nitrate has been found to be an effective therapeutic agent in trachoma but not in inclusion blennorrhoea. Trachoma, moreover, occurs only in the eye and its adnexa, while inclusion blennorrhoea is essentially a genital infection transmitted from the mother to the infant before birth. While there can be no doubt that the two ocular infections are clinically different, any and all of the differential characteristics may be due as much to variations in degree of pathogenicity of the strains of virus involved as to any actual distinctions in species. The inability of both viruses to survive serial animal passage, stimulate immunity and initiate artificial propagation and the resemblance of the respective inclusions suggest that the two viruses fall within the same or

closely related biologic groups. Other authors have considered the infectious agent of inclusion blennorrhoea to be the inclusion body itself. The present study offers no information to support or refute this opinion.

**Phagocytic Activity of Human Leukocytes.**—Hertzog studied the phagocytic activity of the leukocytes from seventeen cases of leukemia, three cases of infectious mononucleosis, four cases of lymphocytosis and two cases of eosinophilia. Staphylococci and streptococci were used as test particles. The mature polymorphonuclear neutrophils showed the greatest amount of phagocytosis both as to the number of bacteria ingested per cell and as to the percentage of cells engulfing bacteria. The monocytes, eosinophils and metamyelocytes were also actively phagocytic. The phagocytic activity of the myelocytes, promyelocytes, leukoblasts and myeloblasts appears to be directly proportional to the maturity of the cell, as there was a marked decrease in phagocytosis in the more immature forms. An exception was found in the histoid stem cell and histoid monoblast of leukemic reticulo-endotheliosis, as these immature cells showed an unusual degree of phagocytosis. Phagocytosis was observed in a small proportion of mature lymphocytes. The degree of phagocytosis increased as the cell grew larger with a corresponding increase in cytoplasm. The leukocytoid lymphocyte of infectious mononucleosis showed the greatest phagocytic activity. Hence, lymphocytes in their prephagocytic stage may occasionally show phagocytosis under experimental conditions.

### Phenobarbital and Amphetamine Sulfate in Epilepsy.

—Cohen and Myerson found that phenobarbital adjusted individually with reference to the rhythm of each patient's seizures reduced the seizures in male patients by 69 per cent; of the ninety-three patients treated eighty-three were improved. Sixty-seven patients showed a 50 per cent reduction of seizures or better. Of fifty female patients forty-five were improved with a total seizure reduction of 61 per cent. Thirty-four patients showed 50 per cent reduction of seizures or better. Amphetamine sulfate (benzadrine sulfate) proved specific in the treatment of ataxia and drowsiness which developed in fifteen patients in the course of phenobarbital medication. The daily dosage of amphetamine varied from 5 to 20 mg. Amphetamine permits the retention of effective doses of phenobarbital otherwise impossible. It does not increase the number or the severity of the epileptic seizures. It has no apparent effect on the blood sugar, nonprotein nitrogen or creatinine or on the basal metabolic rate, pulse rate or blood pressure. There appears to be no necessity for routine catharsis in the treatment of epilepsy when phenobarbital dosage is adequate.

## Postoperative Complications of Cataract Operations.

—Because many complications may be prevented Berens and Bogart analyzed the records of the 1,004 cataract extractions performed at the New York Eye and Ear Infirmary during the last two years. Extracapsular extractions were performed on 702 patients and intracapsular extractions on 302. The most frequent postoperative complications were hemorrhage into the anterior chamber (4 per cent in the intracapsular cases and 1.4 per cent in the extracapsular cases) and loss of vitreous (9.9 per cent in the intracapsular cases and 9 per cent in the extracapsular cases). The other complications, detachment of the retina, detachment of the choroid, suppurative intra-ocular infection and prolapse of the iris, occurred in only a few cases of each series. Secondary glaucoma occurred in seven extracapsular cases; iridocyclitis was observed following seven extracapsular extractions and two intracapsular operations. If the number of postoperative complications is to be reduced, there seems to be little question that the preliminary examination is most important. Careful preoperative study of the patients, combined with the institution of treatment for chronic infections, hyperglycemia, hypertension and other general diseases when found may prevent serious postoperative complications which frequently result in impaired vision or blindness. Careful complete suturing of the wound with a complete but not too wide conjunctival flap seems to be one of the best methods of preventing many serious postoperative complications. In the postoperative care of the patient the most important single factor in preventing complications (other than careful nursing, the treatment of cough as well as other movements which might endanger the eye) is the careful postoperative examination of the eye, especially the avoidance of squeezing by unnecessary or clumsy manipulation.

**Dietary Treatment of Chronic Sinusitis.**—In summary, Shurly points out that the treatment of chronic sinusitis calls for surgical intervention. Dietetic treatment should be used as a therapeutic aid. Prophylactic treatment in early infancy may offer much in preventing bony malformations of the nose and sinuses, through the proper use of vitamin D, particularly in milk, eggs and leafy vegetables. Vitamin A deficiency may influence the resistance to infection, with lowered vitality of tissues, especially in the ear, nose and throat. Vitamin C has a special influence on the mucous membranes of the gums, nose and mouth. The value of raw vegetable juice and mineral salts lies in promoting cell growth and selection. Special attention to endocrine balance with the use of iodine and thyroid extracts is of value in establishing vasomotor tones. Food allergy must be determined by special tests and the history. The prevention of sinus infection at the time of the removal of tonsils and adenoids may require special dietetic treatment and cod liver oil.

**Rapid Control of Intracranial Pressure.**—The method for controlling intracranial pressure that Schmidt recommends depends on mechanics alone, is rapid, and he thinks effective in most cases. The method consists of inserting a No. 6 French ureteral catheter through a trephine opening in the skull. The ventricle is first punctured with an ordinary ventricular puncture needle in order to make a path. Into the ureteral catheter the stylet of the ventricular needle is placed, so as to make it firm. The stylet and catheter are introduced into the ventricle through the previously formed path made by the ventricular puncture. The catheter is anchored with a fine linen suture to the skin. The top of the catheter should be a little above the skin to prevent the skin from closing over the catheter. A 1:2,000 red mercuric iodide dressing is placed over the end of the catheter. If the catheter becomes occluded it is opened by inserting a long needle into it and aspirating. Suppuration may develop at the skin after a week or more and the catheter has to be removed and inserted on the other side. However, the catheter may be kept for longer periods, depending on the development of suppuration at the skin. The author has used this method in twenty-four cases and found it to be of aid in reducing increased intracranial pressure preoperatively and postoperatively, to stabilize patients who have had pressure for some time, to aid in diagnosis, to reduce emergency operations after ventriculograms or in acute or high intracranial pressure, and to heal the skin over a cerebral hernia. Owing to the danger of introducing infection, one must use the procedure carefully and only after weighing the indications.

**Thyroidectomy and Remaining Tissue.**—For a number of years Smith has measured remnants of thyroid equal to those remaining by cutting out portions of corresponding size from the specimens removed and weighing them, thus arriving at an estimate of the amount of tissue left in the neck. Seventy-five patients with diffuse toxic goiter in whom this procedure has been carried out and who have been followed with metabolism tests for from eight months to six years form the basis of his study. The fact that relapses occurred in 13 per cent of the cases, a figure that may well be increased after a longer period of observation, would argue that criticism might point rather toward too great conservatism than otherwise. The estimated size of the remnants of thyroid left in the neck has ranged between 3 and 25 Gm. Thirty-seven were recorded as 6 Gm.

or less and thirty-eight as 7 Gm. or more. The most important factors in planning the extent of operation is the severity of the disease and the size of the gland. When the incidence of persistent and recurrent cases is used as a criterion, the results favored the smaller remnants on the basis both of actual weight and of relative proportion. Examination of the individual failures showed that in no case did the remnant fall into the smaller half of the series on both counts. This indicates that one must be guided in his judgment by the size of the original goiter and in the case of small toxic glands be particularly radical. On the basis of his study the author thinks that a remnant of 4 or 5 Gm. as he has estimated it or, as corrected, 6 or 7 Gm. should result in fewer failures. Blocks of tissue measuring 3 by 1 by 1 cm. seem to be a satisfactory amount of tissue to allow to remain on each side of the trachea in the more toxic cases unless the gland is small. In the case of medium to good sized glands a remnant of 5 Gm. would represent a small proportion of the original goiter, say one tenth or less, a relative amount which in the series studied was followed by a low incidence of postoperative hyperthyroidism. In the case of glands which are little larger than normal, despite a marked toxicity, one should leave smaller amounts than usual so that the relative reduction of thyroid tissue is thorough. In large glands with only mild toxicity, more generous remnants ought to meet the indications.

**Arteriovenous Aneurysms.**—Reid and McGuire present another series of thirty cases of aneurysms (twenty-one arteriovenous aneurysms and nine cirroid), discuss the clinical observations and surgical procedures and supplement these clinical studies whenever pertinent by arteriovenous aneurysms produced experimentally in dogs. Sixteen of the arteriovenous aneurysms were operated on and all of them, except one of pulsating exophthalmos, were cured. In two instances the aneurysms healed spontaneously without operation. All of the nine cirroid aneurysms were operated on; three were cured and the other six were improved. There were no deaths in the entire series. There were eight arteriovenous aneurysms which had caused definite cardiac damage; in two there was severe cardiac decompensation. Of the nine cirroid aneurysms, two showed evidences of some cardiac damage. In every instance in which the heart was demonstrably affected, closure or excision of the fistula was followed by cardiac improvement. In the artery and vein opposite the fistula extensive calcification was noted in the walls of the vessels. In eleven, definite enlargement and thinning of the wall of the proximal artery was present. In many cases the wall of the involved vein was definitely hypertrophied. There was no positive evidence that the circulation time was definitely affected by the fistula. The authors' studies fail to confirm the observations of Holman and others who have reported a large increase in blood volume in cases of arteriovenous aneurysms. Slowing of the pulse rate when the fistula was closed was observed in ten cases and in the experimental animals. The extent of this slowing of pulse rate varied greatly and seemed to be directly related to the seriousness of the cardiac damage and the size of the fistulas. Venous pressures appear unaffected by arteriovenous aneurysms unless there is some evidence of cardiac decompensation, when the changes in venous pressures are similar to those which occur in cases of cardiac decompensation from any other cause. A rise in both systolic and diastolic pressures following closure of arteriovenous fistulas was observed in thirteen cases. That an extensive collateral circulation occurs around an arteriovenous fistula was confirmed in six instances. It is this overabundant collateral circulation which makes the occurrence of gangrene after excision of chronic arteriovenous fistulas practically unknown. The circulation, considerably distal to the fistula, may be impaired as evidenced by absent pulses, coldness of the part, cyanosis and occasional chronic ulcers that will not heal. Nerve paralyses associated with the arteriovenous condition occurred in four cases. Intracranial arteriovenous aneurysms developed in three cases, pulsating exophthalmos in two and a fistula between the ophthalmic vessels behind the eyeball in one. Two arteriovenous aneurysms healed spontaneously. A long period of rest in bed, with elevation of the affected part and the limitation of the intake of fluid, possibly bleeding, soon after the accident, might result in more spontaneous cures. Unless immediate or early operations are required because of

hemorrhage, dangerous hematoma, infection or rapid cardiac damage, it is wise to postpone the operation for from three to six months after the occurrence of the fistula. The essential thing in the operative treatment of arteriovenous and cirroid aneurysms is to eliminate all possibilities of any blood ever again passing through the fistulas. An easy method of making an arteriovenous fistula which can be alternately closed and opened is illustrated.

**Eunuchoidism.**—Carmichael and Kenyon made a clinical study of six eunuchoids from the physical, endocrine and psychiatric points of view. In addition they estimated the urinary excretion of androgen and estrogen and administered extracts of the urine of pregnant women in attempts at therapy. In each instance the development of the secondary sex characters was that of the normal boy aged from 12 to 15. The basal metabolic rate was usually within the lower limits of normal. The patients were thin, fat or of ordinary build. The ratio of sitting to standing height varied from 47.2 to 52.8 per cent, and only one of the eunuchoids, who was very fat, approached closely the average normal value of 52.9. The ratio of span to stature varied from 105.5 to 110 per cent, being in all instances well in excess of the averages for most races cited by Hrdlička. The arms and legs were therefore disproportionately long. The six eunuchoid persons studied showed an average value of 20 international units of androgenic material in the urine daily with the fifteen minute hydrolysis (as compared with approximately 67 international units), with a range of from 7 to 33 units. Seven assays on four of these patients, studied by the two hour hydrolysis method, gave an average of 11 international units, with a range of from 0 to 17 units, as compared with the normal average of 40 units. Thus, no matter what duration of hydrolysis is chosen, the eunuchoid patients excreted about a third of the normal amount of androgenic material. Five eunuchoid patients studied for estrogenic material excreted the equivalents of 2, 2, 1, 2 and 7 micrograms of estrogen respectively, as compared with the normal of 10 micrograms. During treatment with large amounts of an extract of the urine of pregnant women for six months or more there was slight enlargement of the penis and increase in erections in two cases. In one case such treatment was accompanied by definite advances in sexual development at the age of 29, similar to the changes observed in normal boys at puberty; whether these changes were coincidental in this instance or were brought about by the treatment cannot be determined. Psychiatric study revealed nothing characteristic for the group. One patient could be classified as of dull normal intelligence, on the basis of an intelligence quotient of 83 in the Stanford-Binet test. In the remaining cases the intelligence ranged from this point to the intellectual capacity

required for successful college and professional work. The personalities of the patients varied from that of an active, energetic, popular, friendly, successful professional man to that of a quiet, withdrawn, sensitive shy, self-conscious person or of an overfastidious, perfectionistic, pious, ambitious, quiet, reserved man who suffered keenly from his physical inferiority to the point of feelings of reference, depression and suicidal thoughts and who tried to solve his problems finally by seeking refuge in training for the priesthood. The six patients sought treatment voluntarily. It is suggested that psychoanalysis of eunuchoid patients may prove an important contribution to an understanding of the relation of the endocrine glands to mental disorders.

**Endocrine Theories of Dysmenorrhea.**—In studying the problem of dysmenorrhea, Fluhmann determined the estrogenic content of the blood of nineteen women with severe dysmenorrhea. No pelvic or systemic cause for the painful menstruation was found. Eighty-five tests for estrogen were conducted by the mucification test; at least three on each patient were performed at weekly intervals. The blood estrogen of the nineteen patients failed to demonstrate any consistent departure from the normal, either in the amount of estrogen present or in the type of curves obtained. In eleven instances a single peak in the concentration of the substance occurred during the interval and presumably was associated with ovulation. In seven cases the interval rise was present, but a secondary increase also was noted at about the time of menstruation. The only abnormal observation was in a young woman of 19, in whom there was a definite increase of estrogen at the time of menstruation and no peak during the interval. There are serious objections to accepting any of the theories (deficiency of estrogen, excess of estrogen or deficiency of progesterin and overactivity of progesterin) which seek to explain the cause of primary dysmenorrhea solely as a hormone deficiency or excess.

**Inhibition of Lactation.**—Kurzrok and O'Connell injected twenty-one successive patients, in whom it was decided to terminate lactation, with testosterone propionate. The total dose ranged from 50 to 150 mg. Two doses were given daily for one or more days and all injections were made deep in the

gluteal region. The effect in only two instances was considered unsuccessful; one patient was completely relieved of symptoms on the fourth day and the other patient was injected with a total of 75 mg. of testosterone propionate divided into three doses. In the latter case the first injection was given on the first day post partum. The symptoms of pain, fullness and engorgement of the breasts were not relieved. In view of the fact that lactation usually begins on the fourth day post partum the inhibitory effect of testosterone propionate might have been exerted a little too early in this case. The results were excellent in the remaining nineteen cases. It was not unusual to find that, when doses of 25 mg. were given, complete relief of all symptoms was obtained within a few hours after the second dose (eight hours after the first dose). In general, 40 mg. or more of testosterone propionate was required to relieve all symptoms of engorgement of the breast. Complete relief of symptoms usually occurred within forty-eight hours. The best results were obtained from doses of 25 mg. each. Once the symptoms were relieved there was no tendency for their recurrence after the injections were stopped. There were no unpleasant by-effects from the treatment. The normal character of the lochia was not changed. No after-pains were produced. The onset of the first menstrual period was not delayed.

**Sciatic Pain of Unknown Origin.**—Haggart outlines a method of treating sciatic pain that he has employed successfully in the treatment of seventy patients with sciatica of unknown origin. The method is also applicable for immediate

relief of severe sciatic pain while a clinical study is being made to determine the cause. The method is a combination of two, and in some instances of three, procedures: (1) perineural injection of the sciatic nerve with a 1 per cent solution of procaine hydrochloride with 2 drops of 1:1,000 epinephrine to the ounce, (2) traction to the affected extremity by the Russell method and (3) in an increasing number of cases manipulation of the lower part of the back under intravenous sodium ethyl (1 methyl-butyl) thiobarbiturate anesthesia. The objective of the injection, 50 cc., of the procaine hydrochloride is to surround the sciatic nerve with the solution and possibly also to inject its sheath. In addition, the fascia and substance of the piriformis muscle, and in some instances the posterior sacro-iliac ligament, are thoroughly infiltrated. Following injection and manipulation, with or without traction, all patients are instructed in muscular exercise of the lower part of the back and of the gluteal muscles. When the patients become ambulatory, posture training also is given as indicated. Intensive heat and massage are likewise utilized, chiefly applied to the lower part of the back, the region of the buttocks and the upper part of the thigh. Hot fomentations and infra-red rays have been the most effective forms of heat. Of the seventy-five patients, all but ten obtained immediate relief of pain. Thirteen were benefited temporarily for from three to six months. Ten patients were free of symptoms for one year and then did not return or answer follow-up letters. In thirty-eight cases it was eventually possible to make a definite diagnosis and so determine the cause of the sciatica and advise appropriate treatment.

**Gas Bacillus Infection as Complication of Fractures.**—Bosworth states that prophylaxis with both gas bacillus and tetanus antiserum should be the rule in all cases of compound fracture. Amputation should never be done for acute gas bacillus infection, although it may be necessary later because of deformity. Repeated massive doses of intravenous polyvalent serum should be continued until the infection is controlled. Drainage but not débridement should be instituted. Many tissues first thought to be dead will later be found viable. Roentgen therapy may yet prove to be of the greatest help. Orr dressings and treatment may be safely carried out as in any other infection of the bone, once the acute gas bacillus infection has been brought under control, without regard to the presence of *Bacillus welchii* and its associates which remain lying apparently inert in the wound.

**Vitamin D in Chronic Arthritis.**—Steinberg studied the clinical effects of massive doses of vitamin D in the treatment of chronic arthritis and its possible effect on the blood calcium. He administered the vitamin in doses of 160,000 U. S. P. units daily to forty patients with chronic arthritis. Fourteen showed clinical improvement and twenty-six showed no improvement;

the condition of three of the latter group was definitely aggravated. The serum calcium and phosphorus levels of thirty-two patients were determined and it was found that massive doses of vitamin D will lower a high serum calcium; it will raise a low or normal serum calcium to a higher level and then, after continued administration, will again decrease the hypercalcemia level. The clinical improvement or nonimprovement or even aggravation of existing joint symptoms had no bearing on the change of blood calcium. The effect on the serum phosphorus was less marked. The effect of massive doses of vitamin D in chronic arthritis is nonspecific and the occasional improvement following its use is similar to that of the many other remedies employed in its nonspecific treatment. Even though the author feels that no specific virtues exist in such medication, at the same time he believes that its toxicity has been overemphasized, but he does not mean to imply that larger doses than he employed may not be dangerous or even fatal.

**Climatic Factors in Acute Rheumatic Fever.**—Mills presents evidence which indicates that some factor concerned with the movement of major storm areas over the earth's surface exerts a dominant influence in determining the incidence of rheumatic attacks. Attacks of rheumatic fever and rheumatic cardiac disease occur from ten to twenty times more often in the worst areas of the storm zones than in the calm warmth of the tropics. In northern countries their difference in incidence between winter high and summer low is almost as striking as is the regional one. Those afflicted in the North usually show improvement in symptoms on migration to subtropical regions. Such improvement is soon lost when they again experience the northern winter and early spring weather. For lasting benefit they must forego living in the stormy North and take up permanent residence in the subtropics. The more even seasonal distribution of attacks of rheumatic fever between summer and winter in Buenos Aires, reported by Coburn, is of some significance in establishing the etiologic importance of atmospheric instability, especially when such storminess is associated with lower temperatures. When a permanent change of residence is possible the choice region from a climatic point of view in this country is the southern parts of New Mexico, Arizona and California.

Obstetric Syphilis. E. D. Plass, Iowa City.—p. 449.

**Pulmonary Embolism.**—Breslich reports fifty-four cases of pulmonary embolism that were found in the 457 postmortem examinations performed from June 1932 to December 1936. Of these, thirty-seven were in medical and seventeen in surgical patients. In 51 per cent of the cases the emboli were associated with lung infarcts. Only three of the thirty-seven patients in the medical group were 40 years of age or less, twelve of whom were definitely obese, eighteen of normal weight and seven emaciated. The leukocyte counts were elevated in twenty-six instances, also there was some degree of fever during the period of hospitalization. Fever and leukocytosis were present in four patients with recent myocardial infarcts and in two with an inoperable carcinoma. In twelve there were obvious suppurative lesions. In the remaining eight instances the occurrence of fever and leukocytosis prior to infarction of the lung or hypostatic bronchopneumonia was not explained. In only five of the thirty-seven cases were the hearts considered normal at postmortem examination. There were only three sudden deaths due to massive pulmonary embolism in the entire group. In twenty-one of the thirty-seven medical cases lung infarcts were present and associated with small emboli, in nineteen of which there was unmistakable postmortem evidence of cardiac decompensation. Venous thrombi which indicated a possible source of pulmonary emboli were discovered in twenty-six instances. Most of the venous thrombi caused no local symptoms, and in only five cases were they recognized before death. Other recognized sources of emboli were thrombi in the left cubital vein, right subclavian vein and veins of the left thigh in one instance

each. In twenty-one patients with pulmonary infarcts, clinical signs were sufficient to make a diagnosis only eleven times. Several of these were thought to be instances of bronchopneumonia before death. In the remaining ten cases pulmonary infarcts caused no symptoms and were discovered only at post-mortem examination. Of the seventeen surgical patients who died following operation thirteen were definitely obese, two of normal weight and two emaciated. Twelve of the patients were more than 50 years of age, four were 40 years of age or less and one was in the fifth decade. In nine there was either a marked hypertrophy of the myocardium of the left ventricle suggesting previous arterial hypertension or serious coronary artery sclerosis or both. There was one instance of acute myocarditis. In seven cases the heart was considered normal at postmortem examination. Lung infarcts were present in seven, and in five of them there were pathologic changes in the heart resulting from arterial hypertension and coronary artery sclerosis. Thirteen patients died suddenly of massive pulmonary embolism, during convalescence from operations involving the abdomen, pelvis or abdominal wall. Death occurred from two to 111 days after operation, but there were eleven deaths in the first three postoperative weeks. In six of these thirteen cases thrombi were discovered in the pelvic or leg veins. In the other seven cases blood clots became detached from the lining of the veins in their entirety and left no trace of their source. In seven of the seventeen surgical cases extensive, acute or chronic inflammatory lesions other than terminal bronchopneumonia were present at the time of death. Three of the seven showed hypertensive cardiovascular disease with sclerosis of the coronary arteries, while in the others the hearts were normal. Three of the seventeen patients had carcinoma, and in one of these acute myocarditis was discovered at necropsy. In the other two the hearts were normal.

**Honey in Infant Feeding.**—Schlutz and Knott studied the suitability of honey as the source of carbohydrate for ten healthy male infants aged 1 month or less. The period of observation continued until the infants were 6 months old. Formulas for all infants were restricted to either evaporated or dried milk and carbohydrate, with additional supplements of pure vitamin or mineral solutions. The general well being of the infant, the number of stools daily and weight gains have been used to determine the value of honey in regular feedings. Besides these criteria, blood sugar tolerance studies have been employed to contrast the response to honey with that resulting from administration of other common sources of carbohydrate. It was found that honey is easily digested, being absorbed more rapidly than most sugars during the first fifteen minutes after ingestion. It is well tolerated by the infant and does not cause diarrhea. It may facilitate weight gains, since there was a slight tendency for greater average gains daily to occur on lower calory intakes when honey was included in the formulas. It appears that honey should be recommended for wider use in diets of infants.

**Sulfanilamide in Gonorrheal Ophthalmia.**—Michels used sulfanilamide orally in the treatment of fifteen cases of proved gonorrheal ophthalmia. Sulfanilamide was given on the approximate dosage basis of 1 grain (0.065 Gm.) per pound of body weight daily combined with equal amounts of sodium bicarbonate. The average hospital duration of the fifteen patients was 5.8 days. The ages of the patients varied from 5 days to 3 years. Of these, two showed corneal involvement; perforation did not result after sulfanilamide was started. Six of the group showed bilateral involvement. None of the complications attributed to sulfanilamide were observed in these patients. In the two years prior to the use of sulfanilamide in the thirty-two similar cases treated for gonorrheal ophthalmia by the usual methods the average hospital duration was 28.5 days. Corneal involvement occurred in two cases, two going on to perforation. Eighteen patients had involvement of both eyes. Four other patients treated by sterile milk were hospitalized for an average of 16.5 days; none of these showed corneal involvement.

**Atrophy of Liver from Mushrooms.**—Ahronheim reports a case of acute yellow atrophy of the liver due to the ingestion of poisonous mushrooms (*Amanita phalloides*). Besides the changes in the liver, a marked hemorrhagic diathesis and degenerative fatty changes in the kidneys and myocardium were found at necropsy. The complete recovery of the patient's wife, in spite of more severe symptoms, indicates that in her case the principal effect of the toxic substance was outside the liver, probably in the intestinal tract only.

**Treatment for Epidermophytosis of Feet.**—In the treatment of epidermophytosis of the feet Meleady instructs his patients not to use soap and water for bathing them but olive oil during the period of treatment. The patient soaks his feet for twenty minutes in a solution containing two tablespoonfuls

of sodium hyposulfite to 2 quarts of water. Following this his feet are thoroughly dried and then exposed for a period varying from five to seven minutes to the actinic rays at a distance of about 18 inches. While the feet are thus exposed the toes are separated so that the rays can penetrate thoroughly into the spaces between and under them. At the completion of the treatment, the feet are thoroughly dusted with a carefully compounded semianhydrous dusting powder of desiccated sodium thiosulfate enhanced by the synergistic action of thymol and an acceptable base of starch and boric acid with oil of absinthium as a deodorant and the patient is instructed to put on clean socks. Prior to putting on shoes, preferably new, the powder is dusted freely over their entire inner surfaces. The patient is then instructed that prior to retiring he is to remove the socks which he had worn during the day, dust the feet thoroughly with the powder and put on a pair of clean socks and wear them during the night. In the morning he is to change his socks for a clean pair and have another pair with him when he reports for treatment. This routine is followed daily. The average time consumed for the treatment is about two weeks. Twenty-two patients have been treated and all have responded favorably.

**Oral Aspects of Diabetes Mellitus.**—Rudy and Cohen studied the oral manifestations of 403 diabetic patients. Of the patients studied, 138 were advanced in years, presenting edentulous mouths and as a result no dental treatment was necessary. Among the remaining 265 were four children and three young adults who had diabetes of long standing. In six of these the teeth were excellent from the functional point of view, with comparatively few carious teeth and no abnormal tartar formation. In the younger children the eruption of the permanent teeth was normal and in the right relation to their ages. Two of the children who presented normal mouths clinically had incipient parodontal lesions. The seventh patient, a young man with severe diabetes, receiving 68 units of insulin a day, had many carious teeth. He had gingival and parietal abscesses on two occasions, when the diabetes became uncontrolled because of dietary indiscretion or inadequate insulin dosage. As a general rule the adult, dentulous, medically controlled patients who were examined presented mouths which were unclean, owing to lack of oral hygiene, with heavy deposits of both supragingival and subgingival calculus. Roentgenographically and clinically this group has a high incidence of diffuse alveolar atrophy. This is particularly true of the younger age group (25 to 45), in which diffuse alveolar atrophy is not generally attributed to local causes. Patients with acute or inadequately treated diabetes present a characteristic oral symptomatology. It is manifested clinically in the gingival papillae, which become markedly swollen and tender and bleed profusely on the slightest pressure. These patients also present loosening of the teeth. This is associated with pain, especially on percussion. With control of the diabetes the acute inflammatory condition of the gingiva subsides, the loosened teeth become fixed and pain on percussion disappears. Extraction of teeth in the inadequately controlled diabetic patient results in a prolonged period of sup-

uration and pain. Local treatment without attention to the diabetes is futile. Infected teeth may aggravate the diabetes and should therefore be removed. Extraction of teeth should be carried out only on controlled diabetic patients and under the supervision of a physician. Neglect may result in serious complications.

\*Blood Calcium: Its Relation to Certain So-Called Angiospastic Conditions. G. F. Norman, San Francisco.—p. 553.

**Blood Calcium and Angiospasm.**—In 1934 Norman described a peculiar relationship between mild hypocalcemia and idiopathic migraine including the report of a few cases exhibiting convulsive seizures. Vascular spasm was accepted to explain the phenomena observed. This concept has now been extended to designate a preexisting localized vascular irritability probably operative through the sympathetic nervous system and inhibited normally by an adequate level of ionized calcium in the blood. A few patients exhibiting the Raynaud complex in moderate degree, either in association with migraine or independent of this condition, could be segregated into the same group. Close questioning will reveal the frequency of blanching fingers and paresthesias in a large group of patients and the association with migraine is quite striking. The author's series now includes about 200 patients from private practice complaining of biliousness or sick headache with nausea and vomiting, and the results have justified the employment of viosterol to raise the blood calcium. A large percentage of cures has been obtained with no other form of treatment. In the small ratio not completely relieved, a diminution of both frequency and severity of the attacks has occurred, frequently persisting for six months after interruption of the therapy.

**Roentgen Treatment of Granuloma.**—McWhirter divides the granulomas into three groups: actinomycosis in which the diagnosis is established by demonstrating the ray fungus in the discharge, granuloma of the vulva and anus associated with venereal disease, and a group of granulomas in which a causal organism cannot be determined. He has encountered fifteen cases of actinomycosis in the last three years. In the earlier cases treatment with x-rays was generated at 180 kilovolts and filtered by 0.7 mm. of copper. During the last eighteen months a still harder quality beam (250 kilovolts and Thoraeus filter) has been employed. Daily treatments of about 100 roentgens have been given (the dose is varied according to the site treated, the area of the field and the age of the patient) over a prolonged period and the dose to the lesion carried as high as 4,000 roentgens. The author believes that daily treatments are superior to weekly treatments and considers high dosage advisable in order to prevent recurrence of the suppuration. A hard quality beam would also seem advisable, as many of the lesions extend to a considerable depth. Drainage may be necessary if there is much necrotic debris. Of the lesions treated, seven of the eight affecting the face and neck have healed. The unhealed one is recent. Of the four abdominal lesions, three have healed and there is a small discharging sinus in one which is gradually closing in. Healing has occurred in one of the two cases in which the wall of the chest was involved. The condition has soundly healed in the case in which the buttock was involved. All the patients are alive, in twelve the sinuses have healed completely and in the remaining three there is marked improvement. The lesions of anal and vulvar granulomas are very sensitive to x-rays and may disappear rapidly with a single dose of 300 roentgens. Occasionally this requires to be repeated after an interval of a week. Seven patients with such granulomas have been treated and all are well. Granulomas of

unknown origin are serious; four of the seven patients with this type of granuloma are dead. Two others are in poor general health. The seventh patient is fit and well. The mouth, pharynx or neck has been primarily involved in all these cases. The lesions resemble malignant conditions but lack the characteristic induration and are often extensive while yet remaining superficial. In other cases the ulceration has been deep and microscopic examination is necessary to exclude malignant disease. As a rule, the general health of the patient is poor. No fungus has been found in any of the cases. The clinical appearance and history, however, suggest that the condition is produced by a fungous infection.

Corneal Transplantation: Results of a Series of Fifty-Six Operations on Forty-Eight Eyes. J. W. T. Thomas.—p. 740.  
\*Vitamin C in Treatment of Whooping Cough. D. Gairdner.—p. 742.

**Dextrose Tolerance Curves and Obesity.**—Embleton reviewed the 500 cases (242 in males and 258 in females) of obesity in which a dextrose tolerance curve was made during the last fifteen years. No examples of gross endocrine disturbance, with the exception of diabetes, are given. It is possible that the series does not represent a fair sample of the obese population of the country, as the patients came from the better-off classes. Only a small proportion have presented themselves because sugar has been found in the urine. The most striking result from the analysis is the difference between the obese of the two sexes. The men show a total of 73 per cent high curves for all ages, whereas the women show only 35 per cent of high curves. This difference in response to dextrose is still more pronounced if the percentage of high curves is plotted for the various decades. In men up to the age of 35 years the percentage of high dextrose tolerance curves is below 30. After this age a sudden rise occurs, so that between 35 and 45 nearly 80 per cent of obese men show a high dextrose tolerance curve, after which this high level is maintained up to the age of 65 and beyond. In obese women, on the other hand, the percentage of high curves remains low until a decade later, 45 years. The rise when it occurs is less sharp, the highest percentage of high curves (70) not being reached until the decade 55 to 65 years. A striking difference is often evident in the postmortem room. An obviously obese woman may be encased in layers of fat, but within this the body appears healthy and the muscles a bright red and not infiltrated with fat. In the male this is rare; if it ever occurs the musculature is heavily infiltrated with fat. A man is more likely to have a high blood sugar curve if he is 50 per cent overweight than if he is even less than 10 per cent overweight. A woman 60 per cent overweight is not more likely to show a high blood sugar curve than one only 10 per cent overweight.

**Vitamin C in Treatment of Whooping Cough.**—Gairdner used large doses of vitamin C in the treatment of twenty-one children with whooping cough and twenty others served as controls. They were seen as outpatients once a week. Only those patients were included in the series who satisfied one or more (in the majority at least two) of the following diagnostic criteria: (1) Haemophilus pertussis recovered from the cough plate, (2) a typical paroxysmal cough witnessed and (3) a suggestive history combined with the presence of either a sublingual ulcer or a marked lymphocytosis. The dosage adopted was first week 200 mg. daily, second week 150 mg. and third and subsequent weeks 100 mg., given in divided doses. The illness in the treated patients lasted an average of thirty-five days as compared with forty-one days in twenty control patients, a difference which lies within the limits of statistical error. The average

rate of weight gained was practically the same in the two groups. These figures are in keeping with the general clinical impression that there was no striking difference in the course of the disease in the two sets of cases, and the assertion of Ormerod and UnKauf that the paroxysmal period of the disease is shortened "from a matter of weeks to a matter of days" was not confirmed.

### Irish Journal of Medical Science, Dublin

No. 153: 597-644 (Sept.) 1938

- \*Clinical Diagnosis of Congenital Heart Disease. P. T. O'Farrell.—p. 597.  
Tuberculosis of the Male Genital Tract. E. D. McCrea.—p. 614.  
Analeptics and the Bragg-Paul Pulsator. R. H. Micks.—p. 629.

**Congenital Heart Disease.**—O'Farrell lists the following criteria as helpful in the diagnosis of congenital cardiac disease: 1. A clear history of cardiac disease existing from birth or early infancy (in the absence of infection) is suggestive, but it should be remembered that many cases of congenital cardiac disease do not present recognizable features until fairly well on in life. 2. Murmurs and thrills heard and felt at an unusual situation, and not conforming to those produced by acquired disease as regards both the area of maximal intensity and conventional direction of propagation, deserve close attention. When murmurs originate from congenital lesions they tend in adult patients to be constant throughout life, but in children murmurs may sometimes undergo variation and on rare occasions disappear. 3. Cyanosis is a prominent feature only in the cyanotic forms of congenital cardiac disease. Cyanosis in congenital cardiac disease is due to hindrance of access of the blood to the lungs and the presence of a venous-arterial shunt whereby some of the venous blood is short circuited from the pulmonary into the general circulation. The mechanism of congenital cyanosis nearly always implies the presence of complicated malformations of the heart. The cyanosis is not an expression of congestive failure except as a terminal event, and therefore the concomitant signs and symptoms of congestive failure are lacking. Cyanosis in congenital cardiac disease may be permanent, transient, delayed or paroxysmal, depending roughly on the severity of the lesion; therefore cyanosis is of assistance as a means of assessing prognosis. 4. Polycythemia is seldom if ever seen in the acyanotic group of cases, and it is not a constant feature in the cyanotic group. 5. Clubbing of the fingers and toes is an important sign. The degree of clubbing is roughly proportional to the duration and severity of cyanosis; therefore it is seen most characteristically in well marked chronic cyanotic cases. 6. Dyspnea with respiratory embarrassment varies according to the severity of the lesion. Dyspnea is sometimes paroxysmal and, as in paroxysmal cyanosis, recovery is often rapid. 7. Developmental defects in other parts of the body are not infrequently found in association with congenital cardiac lesions. 8. Subacute bacterial endocarditis occurs frequently. It is more common in the acyanotic group, probably because these patients live longer. 9. Juvenile hypertension is of diagnostic significance only in coarctation of the aorta. 10. X-ray examinations are of great importance provided the observations are correlated with the other clinical manifestations. Many congenital lesions show abnormal alteration of the cardiac outline when viewed under the screen. 11. Electrocardiography will only verify or refute the accuracy of a clinical diagnosis, chiefly in respect to deviation of the electrical axis.

\*Homesickness and Immigrant Psychoses: Austrian and German Domestic Servants the Basis of Study. I. Frost.—p. 801.

**Nostalgia and Immigrant Psychoses.**—In the space of six years Frost saw forty Austrian and German domestic servants suffering from mental disorders. Homesickness combined with loneliness and exhaustion comprise the principal etiologic factors producing psychoses among immigrants. Hereditary elements do not figure prominently. Mistakes of identity are common and illusions of resemblance appear to follow the stratifications peculiar to primitive notions of kinship. The forms of mental disorder encountered in the present series of cases comprise acute confusional states, acute schizophrenic conditions, paraphrenia and involutional forms. Rarely reactive depressive and twilight states occur. Endogenous manic-depressive insanity is rarer still. Bodily reactions may be seen in all the foregoing forms; loss of appetite, toxemia and vegetative-nervous changes are most common and are most likely to be found in the acute confusional and acute schizophrenic types of disorder.

Trypanosomiasis Gambiensi: Some Observations in Uganda, and Their Bearing on Prophylaxis. A. A. F. Brown.—p. 296.

**Pellagroid Beriberi.**—In countries in which beriberi and pellagra are endemic, cases are encountered in which symptoms of the two diseases are present concomitantly. To cover these cases Castellani introduces the term "dermoberiberi" or "pellagroid beriberi." In a typical case of pellagroid beriberi the following features are present: 1. The typical symptoms of beriberi present are weakness and paresis of the lower extremities, loss of the knee jerk, stepping gait, pain in the calves on pressure, patches of anesthesia or hyperesthesia, slight pretibial edema, normal pupils and normal urine. 2. Some of the symptoms of pellagra are chronic roughening and pigmentation of the exposed skin, but at times also of unexposed parts of the body and around the anus. At times stomatitis and angular stomatitis may be present. 3. Keratosis pilaris-like eruption, with numerous, often nonpruriginous, horny papules, which give a feeling of a nutmeg grater, are mostly found on the extensor parts of the legs, thighs and arms (the eruption may be limited to the buttocks and lateral parts of the thighs). This is a well known feature of avitaminosis A. These cases are probably due to a pluriavitaminic deficiency.

44: 165-312 (Oct.) 1938

Septicopyemia with *Bacillus Funduliformis*. A. Lemierre, J. Reilly and A. Laporte.—p. 165.

Septicemia with *Bacillus Fragilis*. Mme. Ternois.—p. 201.

Septicemias with *Streptobacillus Moniliformis*. M. Morin.—p. 219.

\*Clinical Study of Forty-Eight Cases of Septicemia with Hemolytic *Streptococcus*. J.-A. Lièvre.—p. 245.

Several Observations on Colibacillemia. R. Roch.—p. 271.

Study of Septicemia with Diphtheria Bacilli with Endocarditis Appearing in Course of Diphtherial Angina. P. Lenti and Mlle. S. Wirz.—p. 293.

**Septicemia with Hemolytic *Streptococcus*.**—Lièvre bases this report on forty-eight cases which were observed at the clinic for infectious diseases at the faculty of medicine in Paris during the years 1933, 1934 and 1935. He says that in the majority of cases the streptococcic septicemia is not a primary disease; it usually is a secondary manifestation in a pathologic process which indicates clearly the way by which the pathogenic agent was introduced into the organism. In only two of the forty-eight cases was the cause not clear. In localized streptococcic infections, such as erysipelas, the streptococcus is likely to pass into the blood. Eruptive fevers likewise may become complicated by streptococcic septicemia. The author observed cases after measles which, however, were complicated with streptococcic otitis or sinusitis. The infections of the middle ear have an important part and tonsillar processes may assume a role. Discussing the symptomatology of septicemia with hemolytic streptococci, the author takes up the mode of onset, the fever curve, the general condition, the cutaneous symptoms and the involvement of the internal organs. In his discussion of the treatment he first cites mortality statistics, showing that mortality rates have been known to reach 90 per cent. In his own material, twenty-four of forty-four patients died, a mortality of 54.5 per cent. Following remarks about general measures, particularly the diet, the author says that the removal of the focus of infection is an important factor in the treatment. He says that the results obtained with serotherapy vary greatly in different reports. The experiences at his clinic have not been encouraging, for of fourteen patients subjected to serotherapy only three recovered. About blood transfusions he says that generally the effect was not clear; it was not harmful and it even seemed to improve to a certain extent the general condition and the anemia. In four cases the blood transfusion had a definite effect on the evolution of the septicemia. This effect became manifest in a rapid decrease in the temperature. The clinical histories of these cases indicate that sometimes blood transfusion may effect a sudden improvement in streptococcic septicemia.

Intramural Pregnancy. S. I. Stern.—p. 193.

**Progesterone in Toxicosis of Pregnancy.**—After calling attention to the increased urea content of the blood in women with pregnancy toxicosis and to the effect of thyroid on this condition, van der Hoeven says that he tried estrogen without satisfactory results. Later he tried progesterone, the hormone of the corpus luteum, and obtained better results. In this connection he points out that an article by Paterson indicates that Paterson also tried progesterone in preeclamptic conditions and found that it improved the general condition and that the symptoms of intoxication diminished without a special diet. It was noted particularly that the albuminuria and the arterial tension decreased and that the edemas disappeared. After stating that Paterson made his studies with progesterone in twelve cases, van der Hoeven discusses two cases of pregnancy toxicosis in which he administered progesterone. Repeated tests on the blood pressure revealed that the progesterone effected only a temporary reduction, for, after a short time, the pressure increased again. The author further cites factors which indicate that progesterone is antagonistic to solution of posterior pituitary and that after treatment with progesterone the uterine muscle becomes less sensitive to

the effect of solution of posterior pituitary. Thus, in order to reestablish the sensitivity of the uterus to solution of posterior pituitary and facilitate normal delivery it is necessary to administer also estrogen. The author reports a case in which he resorted to the administration of progesterone and of estrogen. He reaches the conclusion that by treatment with progesterone and with estrogen it is possible to ameliorate provisionally all the severe symptoms of pregnancy toxicosis, after which it is necessary to provoke premature delivery in the usual manner.

Ureteropyelography in Nurslings. R. Bouchard.—p. 1472.

Angiocardiography in Children. A. Castellanos, R. Perciras and A. Garcia.—p. 1474.

**Electro-Encephalographic Studies in Epilepsy.**—Pagniez and his associates point out that the electrical activity of the normal and the diseased brain has been the object of many investigators during the last few years and that epilepsy has attracted the attention of electrophysiologists more than any other nervous disease. Their studies were made on thirty-three patients with diverse forms of epilepsy, in a small number of whom the diagnosis of epilepsy was doubtful. The electro-encephalograms were made with occipital, frontorolandic, biparietal, bitemporal and temporofrontal derivations (recording not simultaneous). In the course of these studies the authors observed paroxysmal as well as permanent modifications in the electro-encephalogram. They discuss and illustrate some of these modifications. They found that the epileptic patients with violent or frequent attacks and those refractory to treatment or with mental changes showed between the attacks electrical waves of abnormal frequency. In the majority of these cases the dominating frequency was between six and seven per second. Nevertheless, of twelve patients with the severe forms of epilepsy there were two who escaped to a certain extent this considerable retardation of the alpha waves, the predominating frequency being from eight to nine per second. Moreover, all the patients with severe epilepsy (except the patient who had been operated on) showed electro-encephalograms of great or average amplitudes (usually above 50 microvolts). The epileptic patients with less violent and less frequent attacks and those who were benefited by treatment did not show abnormal waves outside the epileptic attacks. Some of these patients, moreover, presented electro-encephalograms of small amplitude. Thus the electro-encephalograms of epileptic patients seem to be the objective indication of the severity of their disorder. This method of examination has not only diagnostic but also prognostic value. Moreover, it can be used for medicolegal purposes in the selection of persons for professions and for military service and in control of therapeutic measures.

**Action of Toad Venom on Heart.**—Lutembacher says that toads were widely used for the treatment of dropsy in patients with heart disease before digitalis was employed. After pointing out that the venom is excreted by the cutaneous glands and especially by the parotid glands of toads, the author reviews the earlier literature on the nature and action of toad venom. He first obtained and prepared the venom and then tested its action. He describes its effect on the heart action of various types of frogs and of rabbits and then describes clinical studies. The clinical observations confirmed the results of the experimental studies, that is they demonstrated that the action of toad venom is inferior to that of digitalis preparations in that it is of short duration. Finally the author demonstrates the immunity of the toad against its own venom. This immunity is related to the resistance of the toad to intoxication with digitalis.

\*Gold Treatment of Bronchial Asthma (Autodesensitization Under Influence of Thiosulfates). I. Vignati, V. Skalak and S. Ranchenberg.—p. 1482.

**Gold Treatment of Bronchial Asthma.**—Vignati and his associates describe clinical observations and animal experiments on the mode of action of the thiosulfates, particularly gold sodium thiosulfate, in anaphylactic conditions. Summarizing

their observations, they say that the antishock effects of the thiosulfates in bronchial asthma are due to the antianaphylactic effect of sulfur. The diverse cations intervene secondarily but they may appear preponderant by reinforcing or reducing the antishock effect of the thiosulfates and by modifying the metabolism of these substances. In the use of gold sodium thiosulfate it is necessary also to take into account the affinity of gold for the pulmonary tissue. In order to obtain a therapeutic effect, the presence of the allergen is necessary; the latter even plays the principal part by intervening at the moment when the thiosulfate effects a temporary desensitization. Its effect is thus produced according to Besredka's method; that is, by introducing intermittent doses into the organism. If the patient lives in surroundings rich in allergen, the desensitization renews itself incessantly and is so prolonged that it presents itself as a lasting disappearance of the sensitivity. It is this circumstance which is responsible for the lasting therapeutic effects. This justifies the assumption that the action mechanism is an auto-desensitization under the influence of the thiosulfates.

\*Ascorbic Acid in Healing of Fractures. G. Giangrasso.—p. 255.

**Ascorbic Acid in Fractures.**—Giangrasso observed the healing of fractures in fifteen cases during the administration of subcutaneous injections of ascorbic acid after reduction of the fractures followed by immobilization or traction. The first injection of 0.005 Gm. of ascorbic acid was administered the same day the fracture was reduced. The following injections of 0.001 Gm. each were given at intervals of three days up to complete healing of the fracture, which was determined by the development of the fracture as shown by roentgenograms taken immediately before and after the local treatment and at weekly intervals in the course of the ascorbic acid treatment. Children received only half the dose given adults. The patients of another group who did not receive ascorbic acid but had the fractures treated in the same manner as the aforementioned patients served as controls. The author found that formation of a strong bone callus, restoration of the functions of the fractured structures and regaining of the working capacity took place in half the time in patients who received ascorbic acid as in those who did not. He believes, therefore, that ascorbic acid accelerates formation of bone callus in fractures and that the treatment is simple, economical and important socially and from the standpoint of insurance.

\*Malformation of Pelvis and Predisposition to Inguinal Hernia. E. Rebusello.—p. 390.

Vaccine Therapy in Association with Chemotherapy with Azo Dyes in Acute Purulent Otitis Media. F. D'Onofrio.—p. 405.

**Malformation of Pelvis and Inguinal Hernia.**—Rebusello measured the length of the inguinal ligaments and the depth and width of the pelvis of eighty-seven men ranging in age from 20 to 68 who were suffering from inguinal hernia of various types. Hernia was bilateral in twenty-six of the cases. Simultaneous observations were made on a group of normal men of the same age as controls. Measures of the pelvis and of the inguinal ligaments were made after reduction of the hernia. The author found that the average length of the inguinal ligament in inguinal hernia is greater than normal (about 14 cm. or more, and 10.5 cm., respectively). Frequently the inguinal ligament is longer in the herniated than in the normal side in unilateral hernia and also longer on the side of the greater than on the side of the smaller hernia in cases of bilateral hernia. The upper transverse diameter of the pelvis is longer than normal (24.2 and 23.2 cm., respectively). The lower transverse diameter of the pelvis is normal or nearly so (30.2 cm.). The pelvis is of funnel-like shape. It is deeper than the normal structure (within 11.6 and 14.5 cm. in herniation, whereas in normal men it is 9.4 cm. deep). According to the author, the malformation of the pelvis predisposes to the development of hernia.

36: 769-864 (Sept.) 1938

Volume of Blood in Normal Children. U. Gallerani.—p. 769.  
\*Blood Urea Clearance (Van Slyke) Test and Ambard's Constant in Children in Normal or Pathologic Condition. I. Biddau.—p. 805.  
Comparative Researches on Chemistry of Blood and Cerebrospinal Fluid in Poliomyelitis. S. Moschini and I. Biddau.—p. 834.

**Urea Clearance and Ambard's Constant in Children.**—Biddau observed the behavior of the Ambard constant and of the blood urea clearance (Van Slyke) in 110 children. The group included sixty-eight normal children and forty-two with renal diseases and diseases other than renal. The author found that the figures of Ambard's constant are the same for normal children as for normal adults (0.042 and 0.107 with an average of 0.07), the standard urea clearance (elimination of urine showing urinary secretion below the augmentation limit which is 1.7 cc. a minute) predominates over the maximal urea clearance (elimination of urine showing urinary secretion equal to or above 1.7 cc. a minute) and the figures of the urea clearance test are lower than in normal adults when the test is made during a period of functional rest of the kidney and almost the same when the test is made during functional activity. This is due to a special functional elasticity of the normal kidney, which is opposite to the functional rigidity of the kidney in pathologic conditions. The urea clearance and the Ambard constant agree in normal children. Low figures of the Ambard constant correspond to high figures of the blood urea clearance test. Both tests show normal renal functions in heart diseases. In lipoid nephrosis the results of the blood urea clearance show normal functions of the kidney whereas those of the Ambard constant show dysfunction (false results from influence of oliguria). In acute glomerulonephritis the figures of the clearance test are low and those of the Ambard constant are high in comparison to those of both tests in normal children. The author believes that the blood urea clearance test has the same applicability, diagnostic and prognostic value in children as it has in adults. The test is not changed by influence of extrarenal factors. It is more reliable than the simple determinations of urea in the blood and the results of Ambard's constant.

\*Ventricular Complex in Electrocardiograms with Deviation of Electrical Axis to the Left. B. Moia.—p. 75.

Systolic Expansion at Level of Heart Ventricles. A. C. Morelli.—p. 97.  
Short PR Electrocardiographic Interval and Notched and Wide QRS Complex Showing Ventricular Asynchronism. B. Moia and L. II. Inchauspe.—p. 114.

Changes of Electrocardiogram in Parathyroprival Tetany. R. Dassen and R. G. Dambrosi.—p. 124.

**Ventricular Complex in Electrocardiograms.**—Moia studied 338 electrocardiograms with deviation of the electrical axis to the left (deep S wave in the third lead and R wave higher in the first lead than in the second lead) in a group of 316 patients. The QRS complex did not measure more than 0.1 second in any of the cases. During the last week the patients were not given digitalis before the electrocardiograms were taken. There were no pregnant women in the group. The electrocardiograms were classified in four different groups according to the behavior of the QRS complex in the third lead. The predominant features in the first group (224 electrocardiograms) were the existence of a short R<sub>3</sub> wave and a deep S<sub>3</sub> wave. The S wave was deep in the second lead in 122 electrocardiograms in the group. The second group (sixty-four electrocardiograms) showed a more or less deep S<sub>3</sub> preceded and followed by small positive R<sub>2</sub> and T<sub>2</sub> peaks (the triphasic complex). The third group (twenty-eight electrocardiograms) showed a deep Q<sub>3</sub> wave with or without changes of the R<sub>2</sub> wave. The fourth group (twenty-two electrocardiograms) showed the M or W ventricular complex. The electrocardiograms showed a normal heart in fifty-four cases in the whole group. The T<sub>2</sub> wave was negative in the electrocardiograms of normal hearts in all cases but three. It was positive in all cases of alterations of the heart. In the latter cases it was associated, as a rule, with a T<sub>1</sub> low or flat and with a deep S<sub>2</sub>. An inverted T wave was frequently seen in electrocardiograms of hearts either normal or slightly damaged. A downward deviation of the S-T

segment in the first and second leads with upward deviation of the segment in the third lead or an inversion of the T wave in the first and second leads showed alterations of the heart, especially enlargement and disturbances of the conductive system. The changes are not related to the type of the QRS complex in the third lead and do not appear in electrocardiograms of patients with slight myocardial alterations. A deviation of the S-T segment toward the largest ventricular deflection of the electrocardiogram or a negative T-S segment in the three leads shows myocardial alterations from disturbance of the coronary circulation. The associated presence of a deep  $S_2$  with a low  $R_2$  or of a small  $R_2$  with or without notchings and a more or less deep  $S_2$  show, in all cases, serious damage of the heart. The latter electrocardiographic changes, however, cannot be considered pathognomonic of either myocardial infarct or coronary lesion.

Ménière's Disease. F. H. Quix.—p. 827.

Metastatic Epitheliomatous Nodules in Evolution of Cancer of Lung. N. Romano, R. A. Eyherabide and A. Danelli.—p. 831.

\*Ophthalmoscopic Sign for Intracranial Hypertension. J. Pereyra Kafer.—p. 835.

**Early Diagnosis of Intracranial Hypertension.**—The sign described by Pereyra Kafer is seen during ophthalmoscopic examination of the fundus of the eye. It consists in the diminution or absence of changes of the retinal venous circulation which are caused by bilateral compression of the jugular veins in the neck of normal persons. The changes consist in an increase of the caliber and darkening of the color of the retinal veins and diminution of the venous pulsation up to complete stopping, as compression advances and the energetic venous pulsation suddenly returns following sudden decompression (negative sign). The retinal circulatory changes do not take place in the presence of intracranial hypertension (positive sign). The author makes the ophthalmologic examinations with an ophthalmoscope for direct vision on the patient seated. An assistant, who stands behind the patient, performs bilateral compression of the jugular veins and subsequent sudden decompression in the course of the examination. The author obtained a negative response in 100 normal persons and a positive one in many cases of intracranial hypertension, fifteen of which are reported. He says that the diminution or lack of response in intracranial hypertension depends on the presence of hypertension of the retinal veins which develops earlier than edema of the optic disk. The sign is positive in intracranial hypertension of any origin. It appears earlier than edema of the disk and is reliable. When intracranial hypertension subsides, the sign changes from positive to negative.

### Archiv für klinische Chirurgie, Berlin

193: 1-753 (Sept. 21) 1938. Partial Index

Recognition of Hereditary Nature of Malformations. O. F. von Verschuer.—p. 185.

Etiology of Congenital Hip Dislocation. Rohleder.—p. 218.

\*Newer Concepts of Acute Pancreatic Necrosis and Its Treatment. O. Nordmann.—p. 370.

\*Treatment of Hemorrhage Due to Esophageal Varices by Ligation of Subdiaphragmatic Venous Anastomoses. C. Henschen.—p. 383.

\*Operative Treatment of Bronchiectasis and Pulmonary Tuberculosis. F. Sauerbruch.—p. 456.

**Acute Pancreatic Necrosis and Its Treatment.**—The process in the so-called acute hemorrhagic pancreatitis, according to Nordmann, is one of autodigestion and not of inflammation. He therefore prefers the name acute pancreatic necrosis. He believes that functional disturbances of the nerves of the blood vessels have a more important part in the causation of the disease than purely mechanical factors. These disturbances lead to the impairment of nutrition of the pancreatic cells, to formation of abnormal albuminous products and to activation of trypsin. Circulatory disturbances and fermentative processes are responsible for the autodigestion of the gland. The activation of trypsin results in the formation of products of high toxicity. At present there are no means of removing or of inhibiting these products either surgically or medically. The first phase in the anatomic alterations in acute pancreatic necrosis is edema not of an inflammatory but of an ischemic nature,

with beginning necrosis of cells. A number of intermediary stages lead to the conversion of the entire organ into one hemorrhagic, necrotic mass. Occasionally the process may be limited to a part of the organ. The author found diastase values increased in acute pancreatic necrosis. He feels, however, that the test is not of decisive value since it may be present in gallstone disease, in renal stones and in rickets. The increase in diastase is found during the first twenty-four or thirty-six hours, after which it rapidly falls. There may be a rise in the blood sugar level because of the destruction of insulin by activated trypsin. High blood sugar always suggests a bad prognosis. The diagnosis of acute pancreatic necrosis becomes suggestive in the presence of a history of gallstone disease, obesity, onset after a heavy meal, initial shock and vomiting of blood. The author points out that there is no point in draining the peritoneal exudate, since the latter is sterile, and while it contains trypsin it does not contain steapsin, which is injurious to tissues. Koerte advised the opening of the lesser cavity, drainage and tamponade in order to protect the rest of the peritoneal cavity. Next, the surgeons resorted to incision of the pancreatic capsule, and Nordmann advised, in addition, the removal of the gallbladder and inspection and drainage of the common bile duct. None of these measures, however, improved his results. The operative mortality has vacillated between 50 and 86 per cent. Nordmann had the experience of finding at operation a circumscribed area of edema in the pancreas, which prompted him to make a favorable prognosis, only to find at the postmortem a total necrosis of the organ. He concluded that operative manipulation of the pancreas aggravated the case. For that reason he and other surgeons have come to the conclusion that the fate of the patient with acute pancreatic necrosis is predetermined from the beginning and cannot be influenced by operative intervention. The author's mortality on the conservative regimen fell from 50 per cent to 24 per cent, Walzel's from 86 per cent to 28 per cent and Haber's from 53.6 per cent to 23.1 per cent. It is apparent that only about one fourth of the patients die if left alone. In cases in which the diagnosis is not certain, the author advises a simple exploratory incision. In the presence of acute pancreatic necrosis nothing should be done and the abdomen should be closed without drainage. In the presence of acute inflammation of the gallbladder with the patient not in a grave shock, Nordmann would remove the gallbladder and inspect and drain, if necessary, the common bile duct, but the pancreas is left alone. Secondary abscesses which may develop in the course of the conservative treatment are treated by incision and drainage. The most dangerous complications are hemorrhage from a large artery and pancreatic fistula. The prophylaxis of recurrence consists in operative treatment of the gallstone disease. The danger of subsequent diabetes is remote, but one should observe in these patients the blood sugar level.

### Treatment of Hemorrhage Due to Esophageal Varices.

—The possibility of surgical intervention in hemorrhages due to rupture of an esophageal varix depends, according to Henschen, primarily on the establishment of a correct diagnosis. The general examination may reveal the existence of a liver or a splenic disease of a type predisposing to the formation of varices, while the history may bring out one or more hemorrhages in the past, recent difficulty in deglutition, and cramplike pains of the esophagus radiating to the back or the sides. Aspiration of the esophagus with a soft thick stomach tube, after the drinking of water, may reveal blood clots. Other means are direct esophagoscopy and roentgenography. The medical treatment consists of a diet, morphine-atropine, introduction of a stomach tube, transfusions of small amounts of blood, tamponade either direct with the aid of esophagoscopy or through a gastrostomy opening, or direct compression with a colpeurynter. The operative measures include the use of the thermocautery, electrocoagulation with the aid of the esophagoscope, or cauterization through a gastrostomy opening (Lund and Foley). Hans Eppinger advised a splenectomy for recurring hemorrhage. This operation, in Henschen's opinion, is indicated in bleeding leukopenic-thrombopenic types of the splenic disease and is contraindicated in high grade polycythemia and in the presence of portal vein thrombosis. The elimination of the splenic venous flow, however, is not sufficient to prevent

a fatal hemorrhage from other tributaries of the coronary gastric vein. The logical procedure in Henschen's opinion is to ligate all the venous channels arising in the portal area and entering into the formation of the periesophageal and intra-esophageal varicose plexuses. This is best accomplished by a low intercostal thoracotomy on the left side extended by an incision in the diaphragm into a transdiaphragmatic laparotomy. Splenectomy may be performed at the same time if indicated by the presence of a leukopenic-thrombopenic state or when ligation of the splenic branches running to the esophagus is technically too difficult. In cases in which the removal of the spleen is hazardous (adhesions in thrombophlebitic splenomegaly) the author advises a partial ligation of the blood supply of the organ in order to bring about an oligemia rather than ischemia of the organ. He ligates the splenic artery and leaves the vein alone so that it may function in removing the products of breaking down of the organ. The author warns that operative intervention in patients with esophageal varices, whether due to liver cirrhosis or to another cause, is fraught with many dangers, such as the conversion of a small effusion into a permanent and extensive ascites or a dry cirrhosis passing into the ascitic phase. These patients are particularly predisposed to infection. Wound infection or postoperative pneumonia accelerates the progression of the cirrhotic disease. A compensated liver cirrhosis may become decompensated. The alcoholic patient is exposed to the danger of postoperative delirium tremens. Other complications are hepatic coma and cholemic bleeding.

**Surgery for Bronchiectasis and Pulmonary Tuberculosis.**—According to Sauerbruch, bronchiectasis develops as a sequence to inflammatory disease of the pulmonary tissue or as a result of trauma. Bronchiectasis in children and in the young was believed to be the result of pneumonia complicating scarlet fever, measles or pleurisy. The congenital dilatation of the bronchial tree as a forerunner of the condition here was not recognized until recently. In operating on young patients the author frequently found the bronchiectatic disease limited to one lobe. The finding of a dilated bronchus with hypertrophied or callous walls amid normal pulmonary tissue pointed to the congenital nature of the bronchial dilatation. Careful microscopic studies confirmed the gross observation. Congenital dilatation of a bronchus per se is innocent. It becomes pathologic only when, as a result of a superimposed inflammation, the secretions cannot be coughed up from the dilated sacs. This leads to continued suppuration and the development of bronchiectatic disease. Mechanical narrowing of the thoracic cavity by rib resection or filling could be effective in bronchiectasis of inflammatory etiology. Bronchiectasis of congenital origin demands more radical therapy, namely the removal of the involved lobe. The operative treatment of pulmonary tuberculosis is based on the concept that the latter is a general constitutional disease. The paravertebral thoracoplasty with resection of the first to the tenth or the eleventh rib was developed as the result of careful anatomic studies. In his own clinic the operation had a mortality of 2.3 per cent and a cure in from 60 to 80 per cent when the disease was limited to one side. In less carefully selected cases the proportion of cures amounted to from 40 to 42 plus 30 per cent of the cases which showed improvement. In 1,600 cases in which there were broader indications for operative intervention the mortality was 6 per cent and the cures 40 per cent. The operation of filling, first conceived by Tuffier as pneumolysis and later developed by Baer as a paraffin filling, is useful in the treatment of hollow spaces in cured tuberculosis and again as an aid in unsuccessful thoracoplasties. The method was found to be particularly valuable in the treatment of productive cirrhotic process of the upper lobe with small but stiff-walled cavities. It may be applied in severe acute hemorrhage, and it made possible the operative treatment of bilateral involvement. In the treatment of cavities it is important to recognize two types, the early cavities with elastic circumference and the rigid cavity of tertiary phthisis. The author sees much advance in partial thoracoplasties limited to the seat of the disease. Among the important recent concepts he emphasizes that of Ranke, who called attention to the dependence of anatomic tissue reactions on allergy and the immune-biologic status of the body.

\*Acute Otitis Media and Nephritis. W. Giese.—p. 159.

**Acute Otitis Media and Nephritis.**—Giese studied twenty-seven cases of nephritis in patients with acute otitis media, which were observed at the otolaryngologic clinic of the University of Jena during the years from 1932 to 1937. These twenty-seven cases of simultaneous nephritis and acute otitis media represent 2.45 per cent of the 1,103 cases of acute otitis media which were treated during that period. Among the 403 cases of chronic otitis media, nephritis was never observed. The twenty-seven cases of concurrent nephritis and acute otitis media are classified into four groups, which differ greatly as regards type and course of the disease. In the first group of seven cases an acute nephritis developed in addition to an acute otitis media. The nephritis developed either several days or several weeks after the onset of the otitis media, usually following after a new attack of general infection, which was recognizable on the increase in temperature. Generally the nephritis is independent of otitis media, but it may originate in the ear as the result of a surgical trauma by way of the blood stream. In the second group of two cases an acute nephritis became complicated by an acute otitis media. These cases were characterized by a severe disturbance in the general condition. The otitis media developed independently of the nephritis but, as a result of the inadequacy of the defense powers of the organism, the otitis media developed sooner than would be the case otherwise. In the third group, which comprised sixteen cases, acute otitis media and acute nephritis developed simultaneously, frequently accompanied by diseases of other organs, particularly the rhinopharyngeal organs. The general condition is extremely poor. It cannot be determined from the outset and the course of the disease whether the nephritis is dependent on the otitis media. In the fourth group of two cases an acute otitis media developed in addition to a chronic nephritis. Observations revealed that the aural and renal diseases concurred and did not influence each other noticeably. Thus a real dependence of the nephritis on the otitis media cannot be detected in all cases and the author rejects the notion that acute otitis media is a focal infection. The concurrence of acute otitis media and nephritis as well as of other local diseases is the result of a general infection which is frequently of tonsillogenic or pharyngogenic origin. The concurrence of oral and renal disease makes no essential difference in the therapy. Surgical treatment is not necessarily more urgent or more frequent. Treatment of the ear exerts little influence on the severity or the course of the nephritis. The ear and the kidney should be treated in the usual manner and a thorough general therapy should be combined with the treatment of these organs.

\*Sugar Content of Cerebrospinal Fluid and Its Relation to Blood Sugar in Healthy Persons and in Patients. A. von Bothmer.—p. 754.  
Influenza and Weather. J. Bauer.—p. 778.

**Sugar in Cerebrospinal Fluid and Blood Sugar.**—Von Bothmer mentions the diurnal alimentary and emotional fluctuations of the blood sugar and calls attention to the fact that the fluctuations in the sugar content of the cerebrospinal fluid occur later and are weaker than those of the blood. Then he discusses the factors which influence the exchange between blood and the cerebrospinal fluid. In the second part of his

paper he takes up the relation between the sugar content of the cerebrospinal fluid and that of the blood under normal conditions and in the third part he discusses this relationship in the course of diseases. The normal range of the sugar content of the cerebrospinal fluid and the normal ratio between the sugar content of the cerebrospinal fluid and that of the blood was determined on 105 healthy persons. To determine the conditions in pathologic processes, 378 examinations were made simultaneously on the cerebrospinal fluid and the blood of patients with various diseases. In his studies on normal persons the author found that, as the sugar content of the blood increases, the sugar content of the cerebrospinal fluid also shows a tendency to increase; that is, it is impossible to talk of a normal range of the sugar content of the cerebrospinal fluid which is independent of the blood sugar. However, the ratio between the sugar content of the cerebrospinal fluid and that of the blood is not constant. It is higher in the cases with low blood sugar values than in the cases with high blood sugar values. The author's observations on the ratio between the sugar contents of cerebrospinal fluid and blood differ from those of some other investigators. His opinion of the sliding adjustment of the normal ranges suggests that the active secretory function of the ependyma of the plexus has a tendency to aim at a "normal" height for the sugar content of the cerebrospinal fluid. This secretory function is strong when the blood sugar is low, weak when the blood sugar is high. However, the secretory activity is counteracted by physicochemical forces, which apparently are responsible for the fact that even in case of increased blood sugar content the ratio between the sugar contents of the cerebrospinal fluid and of the blood does not fall below a certain absolute value. The author's studies in pathologic conditions revealed that the determination of the ratio is of greater diagnostic significance than is the determination of the absolute sugar content of the cerebrospinal fluid. Reductions in the ratio occur in tuberculous meningitis, purulent meningitis, influenzal meningitis and syphilitic meningitis. Increases in the ratio are not specific for certain diseases and consequently are of slight value for the differential diagnosis; their diagnostic value lies in the fact that they usually indicate a diffuse and severe cerebral lesion.

\*So-Called Traumatic Thrombosis in Axillary-Subclavian Vein. E. Roelsen.—p. 889.

Biologic Establishment of Vitamin C in Woman's Milk. P. W. Bræstrup and H. Lieck.—p. 913.

**Traumatic Thrombosis in Axillary-Subclavian Vein.**—Roelsen says that in this disorder there is an acute venous stasis, in part recurrent, manifested by marked venous dilatation and diffuse swelling of the upper extremity. The pathogenesis is uncertain. The syndrome is usually due to preceding overexertion or movement of the arm causing strain, also presumably to certain predisposing anatomic variations in the conditions about the course of the axillary-subclavian vein over the first rib. The mechanism is believed to vary somewhat in different cases. Thrombus formation must be considered a complication, most often due to certain predisposing changes in the wall of the vein or to more or less latent infections; it is not the main cause. The syndrome as a rule occurs in younger, healthy persons without preceding disturbance, particularly in men, and especially on the right side. The general condition is usually not affected. On complication with thrombosis there is often a slight rise in temperature. Complete restitution is the rule, but the time required varies from weeks to months and years, depending partly on the treatment. As long as the venous stasis or the tendency to recurrence persists, the condition invalidates manual laborers up to one third of the normal ability. The author advises first the trial of conservative treatment. Venolysis and denudation of the wall of the vein can be attempted in resistant cases. As a last resort venesection can be tried. The theoretical basis for the operation is not yet clear. Seven personal cases are reported, of which three were treated operatively.

Casuistics from Surgery of Jaw. J. Foged.—p. 1015.

\*Treatment of Patients with Acute Suppurative Otitis Media, with Special Regard to Value of Syringing with Alcohol. V. Schmidt.—p. 1018.

\*Treatment of Patients with Acute Suppurative Otitis Media by Syringing with Alcohol. A. Jørgensen.—p. 1022.

Röntgen Treatment of Chronic Medical Disorders of Joints. S. Heimd.—p. 1027.

Spiritism as Causative Factor in Psychic Disturbances. H. Reistrup.—p. 1031.

**Alcohol for Otitis Media.**—Schmidt says that in acute inflammation of the middle ear treated by his method the functional results, without after-treatment with the air douche, have been particularly good, the number of operations small, the mortality low and the average hospitalization not longer than with other conservative treatment. Early paracentesis is called for, after which hot compresses are applied for twenty-four hours. Syringing with 33 per cent by volume or 27 per cent by weight of alcohol at 37 C. is then begun. A record syringe of from 10 to 20 cc. is used, with a rubber disk attached to the cone and held to the external ear. The fluid reaches the tympanum under a certain pressure by which the discharge on the tympanum is more readily removed with the fluid as it flows back to the disk. Individualization is necessary as to the frequency and number of treatments. In rare cases irrigation three or four times a day suffices, six times daily is the rule, and more frequent daily flushings are given in cases of high temperature and a tendency of the paracentesis opening to close. Paracentesis was repeated in less than every tenth patient. The patients often notice alcohol in the rhinopharynx, which shows that the eustachian tube has become passable, favorably increasing the drainage of the middle ear, with simultaneous rapid improvement in hearing. Syringing with 27 per cent alcohol causes pain only when the treatment is delayed, so that the canal is raw. If there is pain from the mucous membrane of the middle ear, a 2 per cent solution of nupercaine is added for the first days. The author asserts that as far as he knows the combination of disinfection and astringent action with improved drainage of the middle ear through syringing with alcohol is not attained by any other agent. Of the 103 patients treated in 1936 twelve, or 11.7 per cent, were operated on; of these eight had mastoiditis on admission. After-examination in 1937 of 218 patients, most of whom had been observed for more than a year, showed that neither mastoiditis nor other complications had followed. In 210 cases the tympanum had healed, in twenty-five with small cicatrices, mostly linear; in five cases there were small, sharp-edged perforations, with normal hearing, in one a larger central perforation, in two a moist inner ear. Hearing was normal in 208 cases. In the complete material of 295 cases from the period of treatment with syringing with alcohol the mortality was about 1 per cent; two of the three patients who died were operated on immediately after admission.

**Treatment of Otitis Media with Alcohol.**—In the course of a year all of Jørgensen's patients with otitis media were, if immediate operation was not indicated, treated by syringing with alcohol according to the Schmidt method, either twenty-four hours after paracentesis in recent otitis or from the day of admission in cases of spontaneous perforation or paracentesis done before admission. There were 357 patients, with 509 cases of acute suppurative otitis media. In three cases treatment had to be terminated because of unbearable pain in connection with the syringing, in most cases there was pain from two to five minutes after irrigation, especially during the first days, and a few patients felt no pain. In 247 cases recovery resulted; in about two thirds of these the treatment was begun twenty-four hours after the incision of the eardrum, in one third at a later stage. Seventy-five patients, or 29.3 per cent, were operated on in spite of the treatment. The 410 patients with 584 cases of acute suppurative otitis media from the preceding year constitute the control material. Of these 37.8 per cent were operated on. The author sees as drawbacks the need of hospitalization, the painfulness of the treatment and the long duration of the treatment; the advantages are the reduced number of patients operated on, the infrequency of a second paracentesis, the absence of eczema in the middle ear and external ear, and the possibility for direct effect on the middle ear and the eustachian tube.

## Medicine and Civil Government

HAVEN EMERSON, M.D.

NEW YORK

No longer ago than 1910 the students of the University of Edinburgh were congratulated by Sir William Osler on the unexcelled thoroughness with which the prevention of the acute infective fevers had been carried out in Scotland and the fact that the death rate of their city was among the lowest in Europe (15.3 per thousand). And yet if our New York Metropolitan Area should now suffer from such high rates as then and there prevailed, great would be the medical and social consternation, hysterical the publicity, and high the probability of a change of city government.

If a drop in the death rate from 15 to 10 per thousand of the population could express so considerable an alteration of professional and public attitude and such a different perspective in social conscience and ambition, what may have been some of the enduring and effective factors? Among these we like to think that society has become more sensitive to human suffering and that government has responded to social influences.

As Dr. Osler said, "The human heart by which we live has been touched as with the wand of a Prospero. What availed the sceptered race! What the glory that was Greece, or the grandeur that was Rome! Of what avail even has been the message of the gospel, while the people at large were haunted by fear and anxiety, stricken by the pestilence of the darkness, and the sickness of the noonday?"

So, the much beloved master of modern medicine saw the picture but little before you, our students of today, were born.

Now with the intervening record of war and confusion, both ethical and material, we cannot say as he did that "The outlook for the world as represented by Mary and John, and Jennie and Tom, has never been so hopeful." It is for us here and now to challenge as he did then "the dour dyspeptics in mind and morals who sit idly croaking like ravens—let them come into the arena, let them wrestle for their flesh and blood against the principalities and powers,

represented by bad air and worse houses, by drink and disease, by needless pain, and by the loss annually to the state of thousands of valuable lives—let them fight for the day when a man's life shall be more precious than gold. Now alas! the cheapness of life is every day's tragedy."

### THE PUBLIC HEALTH

The social change of outlook grew in strength with the spreading net of knowledge of the quantity and causes of preventable sickness and death. This took practical form in nations, states and cities within a score of years in the middle of the last century, by the action of voters and legislators who determined to include within civil government those functions devoted to protection of the general health of the population, so far as this could be achieved by the application of public authority, the employment of appropriate personnel and the expenditure of tax money. This marriage of the medical sciences to government has, it would seem, been among the highest achievements of mankind in his ever increasing social ambition to master the safety of his body and soul as well as to build a security for his goods. As one moves about in spirit or in fact among the nations the suspicion is strengthened that, of the three gospels, that of man's body is on the whole better served than are those of his spirit or his material wealth, and yet the concern of government with men's bodies has been of more recent origin than its interest in their credos or its control over their tangible property.

While various ancient civilizations have left material records of their intelligence in matters of cleanliness for the person, the home and the city, and in spite of the hygienic regulation of individual and social conduct by religions and dynasties of distant times, the permanent continuous use of the knowledge of human biology within the structure of civil government is a matter of such recent origin as to be almost contemporary with the present most productive era of the medical sciences.

Even the classic treatise of Johann Peter Frank in 1777-1778, when he completed the

Opening address before the Columbia University College of Physicians and Surgeons, Sept. 28, 1938.

publication in Mannheim of his "System einer vollständigen medicinischen Polizei," was too far ahead of his times to have any tangible effect on the forms or functions of the government of the Palatinate or the kingdom of Bavaria.

It was the "Gesundheits Catechismus" of Bernard Christoph Faust that for some forty years after its publication in 1785 became a part of the elementary school education in Würzburg, Darmstadt, Cassell, Hanover and Hamburg. But this did not involve any substantial innovation in government or initiate new functions, merely expanding and formalizing a part of the school curriculum and clarifying the essential elements of the teaching of hygiene. It was not until 1848 when the parliament of Great Britain wrote its first public health law that there was incorporated in this form and duty of public service that element which has so amazingly influenced human life around the world.

#### BASIC FEDERAL STATUTES

While the germ of our own federal public health service, first so named officially in 1912, appeared in the obligation of the Treasury Department in 1789 to provide for the medical care of merchant seamen, it was not until 1893 that the Congress enacted those basic federal statutes on which the inclusive and ever broadening duties with which we are now familiar are based.

The first state department of health was established in Massachusetts in 1855 and the first metropolitan board of health with powers sufficient for all emergencies and essential functions was created by act of the legislature of New York in 1865.

It is with proper medical humility that we recall that it was the lawyer, actuary and secretary of the Poor Law Commissioners of England, Edwin Chadwick, who provided the survey of 1838, stimulated public response and developed support for the first national health law, and another lawyer and student of vital statistics, Lemuel Shattuck, who made the commonwealth of Massachusetts conscious of her health hazards and with his survey of 1854 brought the need of the public to the legislators' attention. Again it was the lawyer Dorman B. Eaton of this city who drafted the law of 1865 under which the Metropolitan Board of Health of New York operated and did it so well that it has been the model of many successors across the continent. The facts about life and death in this city, and the principles on which a modern municipal department of health was created, developed out of the famous sanitary survey conducted largely by the voluntary services of teachers and graduates of our College of Physicians and Surgeons.

It has been notable that parallel with the constantly expanding functions, best or only to be served by government for protection of the

public health, there has been a rapid broadening of those of the private physician in both teaching and applying for the individual and family the precepts and procedures on which the best results of governmental activities in the last analysis inevitably depend.

It is notable that those forms of government most broadly based on the participation of men and women in the conduct of their own local and national civic affairs have been most responsive to the demand of the public for a constantly expanding use of the most recent discoveries of the biologic and medical sciences through government.

Authoritarian government seems to have lacked something essential in its application of science for human betterment. The records of the best national health are where the student, the teacher, the private and public practitioner of human biology, the doctor of medicine, are least hampered by administrative restrictions and the health officer of government is closely responsive to the informed social and professional opinion of his community.

#### GOVERNMENT AND MEDICINE

Many and varied have been the definitions of the objectives sought by the combined sources of government and medicine in the interest of health, from exuberant all-inclusive utopian expressions to the more modest goal of the professional worker. It was Sir George Newman, the distinguished former chief medical officer of the British Ministry of Health, who, as guest of the Academy of Medicine of this city, expressed briefly his most ambitious hopes for the function of the sciences and arts of preventive medicine, "To build a better tabernacle for the soul of man to inhabit," truly a high ideal for a profession or a state.

In its simplest terms public health consists in the application of the sciences of preventive medicine through government for social ends, and it is with this that we are concerned. At the moment sound distinctions between the functions of government and those of the independent and the responsible private practitioner of medicine are in some danger of being swept away in a wave of immature emotional, if not actually political, governmental dominance, implemented by the power of redistribution of the amount and objects of public expenditure for health and other medical services, and are threatened with extinction by the ponderance of federal opinion and tax resources.

There is perhaps still time, though barely enough, to bring to the present problems of medicine and government that slow careful study and trial which has served social evolution so well in the past.

It should be noted that while almost a century of experience with official services,

demanding and gladly accepted by the public and maintained by taxes for reducing the hazards of life by the application of preventive medicine, has made clear the distinction between what each of us can, should and must do ourselves, individually, to promote our health, and what can be done for us only by government, or at least at less cost through public service, there is neither the experience nor any substantial evidence to justify the belief that the entry of government extensively into the practice of curative medicine would achieve results comparable in the scientific, social or economic sense with those attained in public health.

Medicine, whether curative or preventive, has more to contribute than it has ever been able to deliver in the past, and by wise organization certain still greater benefits may be assured; but to reason from the productive success of preventive medicine through government for social ends that diagnosis and treatment of the individual medical and surgical patient by or under the professional and financial control of government would similarly advance social ends or the quality of medical care, or reduce its cost, is not only questionable but on its recorded performance elsewhere is at least improbable.

#### OUR PRESENT HEALTH STATUS

It is well to pause a moment before forming a fixed opinion or committing ourselves irrevocably to a repetition of the blunders and complexities which have arrested the progress of medicine in some other lands and consider the eminence of our own present health status. Certainly no 130,000,000 people under one government or federation of states, and no aggregation of populations representative of such different races or distributed so widely under varied conditions of climate, occupation and economic status have in the recorded history of man enjoyed such relative certainty as our people of the United States do today in the survival of their offspring in infancy and childhood, or have experienced so low an incidence of the communicable diseases or so high an average level of life expectancy. And yet in the most recent official declaration from technical committees and interdepartmental boards in Washington we read that "preventive health services for the nation as a whole are grossly insufficient."

In spite of the fact that no other such continental population has built and served hospitals so lavishly, it is true that some backward and impoverished states and particularly scattered rural populations have not yet been reached by institutional care for general illness, which is now within an hour's motor ride of more than 98 per cent of our people. These same unfavored areas lack also almost all the other conveniences and safeguards, amenities

and cultural advantages of more fortunate regions of the nation. Perhaps time, patience and ingenuity in thrift are needed more than any such vast expansion of hospitals as is proposed by the federal government.

While the honest medical Diogenes searches, and generally in vain, to find persons really needing and wanting but not receiving medical attention, those who use the flood lights of unlimited publicity rather than the discriminating lantern of knowledge suddenly wring our hearts and amaze our international neighbors with the statement that "one third of the population, including persons with or without income, is receiving inadequate or no medical service." It has been estimated that about one third of our population patronizes the charlatan, the quack and the practitioners of therapeutic cults. Perhaps it is this fraction of our people that is referred to by the spokesmen of the federal government, though their words imply failure of the organized profession of medicine.

How can we add to a proper humility, as disciples of Aesculapius, acknowledgment that the abracadabra of legislation and the pompous self sufficiency of bureaucrats can and will do for one in three of our people what we as physicians have failed to do in response to the call of the sick for help?

May we not for a moment play the role of economists or sociologists and answer the fourth item of indictment with which the so-called National Health Program is launched?

"An even larger fraction [i. e., more than one third] of the population suffers from economic burdens created by illness."

Is it possible that economic confusion has been created by international fear and distrust, by class hatred encouraged by the very government that should serve all classes, by a long accumulating disproportion between the capacity of industry to produce and of the wage earner to consume, and that much illness is the sequel of economic burdens rather than chiefly their cause?

#### SUCCESS IN LIFE SAVING

It could probably be statistically demonstrated that preventive medicine has saved from diseases and deaths which afflicted our grandparents' generation in this country about as many persons now living as constitute the great army of the unemployed and unemployables. Our very success in life saving has certainly been a factor in creating a surplus in the labor market.

The phenomena we are facing in the relations of medicine to government, to society, to economics, to federal taxation and federal subsidies for purely local needs are too unfamiliar to the public, to the medical profession and to the Congress to permit us to accept as if final or con-

clusive the evidence offered by a technical quintet, none disciplined by or experienced in the responsibilities of independent medical practice, or by a sextet of appointed executives whose attitude cannot fail to be responsive to the expediencies of their own and their chief's political careers.

It has been said that "untroubled certainty and assured consistency" may be vouchsafed only to those who are not wholeheartedly committed to the scientific attitude of mind in the solution of their problems.

It is well known that government is a large participant in the dual system of institutional care of the sick, almost to the exclusion of private care in the management of hospitals for tuberculosis, mental diseases and those of acute communicable character, and for general illness among persons unable, at least when sick, to pay for medical attendance and hospital care. The safety and chief merit of any hospital service is the tradition and effective practice of medical staff control of policies and standards of professional care of the patients. The medical board and the clinical pathologic conference are instruments of superior value in preventing laxity in medical and surgical performance, whatever may be the limitations imposed by administration.

The same delicately adjusted balance of reciprocal functions of the government and the individual physician as exists in the main in the field of public health will have to be recognized, accepted and stabilized by law and practice in the general care of the sick before we shall have a sense of freedom from threat of government destruction of the individual practitioner of medicine, on whose broadly conceived functions the best in modern life depends.

#### OFFICIAL HEALTH AGENCIES

Whether in the simplest form of township, county or little city organization for health, or in great states, nations or in the Society of Nations, there are but half a dozen functions of government carried on by the work of official health agencies, which have everywhere been found necessary, to supplement the efforts and resources of the individual practitioner in relation to the families he serves. Within the definition of organized care of the sick there are as many as eight fields of service now occupied by governmental and voluntary agencies, and in each of these the control over quality of care of the sick properly rests with the professional staff responsible for the diagnosis and treatment.

Specious arguments are commonly offered, based on the fact that we have common services of police, fire, public conservancy of streets, water and sewage, and that we accept public schools for the compulsory education of

our children, to persuade us that similarly tax-supported and officially administered services for sickness should be conducted by government, wholly or in part at the taxpayers' expense.

While the assistance of government may be useful, although not essential, in facilitating thrifty practices of the family in providing by periodic prepayment for the calculable incidence and necessary costs of disease, there is no reason in the experience of other countries now or in the past to justify us in creating a compulsory contributory system of support for medical care in which the physician and the patient no longer enjoy free choice of economic and professional relationship.

We can afford to take the problem piecemeal, test new devices of governmental participation, measure results in terms well tried in experience, and avail ourselves of the forty-eight experimental fields of civil government which our states offer, before plunging headlong into some national program, ill adapted to the infinite variety of our needs and resources, under the pressure of political expediency and visionary hopes.

Representative government and medicine have been partners in well doing too long to have their initial concern interrupted by temporary differences of opinion or judgment. A doughty individualist, a colleague in physiology from a sister university, has recently taken the opportunity of a tribute to the late S. Weir Mitchell to make the query "Is it not true that, when men have bartered their personal freedom for collective security, they have lost freedom without gaining a security worth having? Is it not a fact that cave fishes have some security—but no vision, while the eagle has scant security but enjoys both vision and wings?"

#### RELATIONSHIP OF TEACHER AND PUPIL

And so we start another season of that academic association so dear to scholars, and your teachers indulge in the perennial renewal of their confidence in human nature through their privilege of converse with you, their fellow students, separated only by the accident of age. Let me, on behalf of your teachers, express my acknowledgment of our debt to you and your successors, by contact with whom alone we continue to play our part in this collegium, of which I am reasonably sure you will grow to be inordinately fond.

Bear in mind the experience of our own particular medical philosopher, Sir Thomas Browne, who in introducing himself to his reading public said:

Now for my life, it is a miracle of thirty years, which to relate were not a History but a piece of Poetry, and would sound to common ears like a Fable. For the World I count it not an Inn but an Hospital,

and a place not to live in but to dye in! The world that I regard is myself, it is the microcosm of my own frame that I cast mine eye on.

Surely Sir Thomas Browne would have rejoiced to hear the words of a modern manufacturer of motor cars who warned the students of a Michigan college of the hazards of today: "Your battle is against the most insidious and tireless of foes . . . the wishful thought, the tempting short cut, the shallow assumption, the clever expedient, the evasion of responsibility, . . . and the specious solution, . . . the surrender of independence and integrity of mind."

Permit me in closing to relate a personal episode from which my earliest interests in medicine and government developed:

In September 1895, when I began the daily walk from my home at Twenty-Eighth Street and Madison Avenue to our college on West Fifty-Ninth Street, I spent many an evening and all free week-ends until Election Day soliciting

votes for the anti-Tammany ticket, as election district captain in the old and notorious "Tenderloin" district, under the direction of the district leader, now the president of our university. This was my initiation to the concern of our profession with public affairs.

You, the students of today, walk the brief space from Bard Hall or the subways and take for granted the general honesty and increasing competence of our city government. You see at last included in our educational community a municipal health center, the material symbol of a participation of government in applied medicine.

I beg of you, the elder workers in this sanctuary, to be patient with the clatter and dirt, the noise and shadows of the new home of the youngest specialty of the medical sciences, the Institute of Public Health, and its collaborator in the training for the governmental services of medicine, the city of New York.

## Comments and Reviews

### STUDENT JOHN SHAW BILLINGS

The experiences of medical students sometimes contribute to the development of powerful ideas. A notable example was an experience of student John Shaw Billings, the centennial of whose birth was celebrated this year. Billings was born in southeastern Indiana and was graduated from Ohio Medical College in Cincinnati in 1860, after earning his way by residing in the hospital and later taking care of the dissecting rooms of the college. In writing his graduating thesis on the results of surgical operations for the treatment of epilepsy, he found it was practically impossible to review the literature. In order to find the data in their original form, he consulted many books and ransacked libraries in Cincinnati, Philadelphia and New York. After six months of such harrowing work and correspondence, he learned there was then not a medical library in the United States in which a student could find a large part of the literature on any medical subject. It was necessary for investigators to visit the capitals of Europe to be reasonably sure of having seen all the reports made by previous investigators on a given subject. It was this experience, Billings said some thirty years later, that caused him to try to establish for American physicians a complete medical library and an index of medical literature which would spare investigators the impossible task of consulting thousands of texts to find a few references. Thus was born the idea from which developed the greatest medical library in the world today, the Army Medical Library in Washington, D. C.

After graduating, Billings began to practice in Cincinnati; but in a short time the Civil War came along and he entered the Medical Department of the United States Army, serving at the battles of Gettysburg and Chancellorsville, in field hospitals, and in hospitals in New York harbor. In 1864 he was detailed to the Surgeon General's Office in Washington, and here his genius found an opportunity to develop. The Surgeon General's Library at that time comprised 2,253 volumes. A fund of about \$80,000, left over from the Civil War hospital funds, was entrusted to Billings in 1868 to use for the improvement of the library, and at once he embarked on the great work that eventually was to make it possible and practical to review the medical literature. He began collecting and cataloguing and in 1872 published the first Catalogue of the Surgeon General's Library, which comprised 454 pages with a supplement of twenty-six pages. Two years later he published a three volume catalogue. His vision, however, was much broader. He wanted a catalogue in which under the names both of authors and of subjects the literature of the world would be indexed. He prepared a specimen and submitted it to leading members of the profession throughout the country in 1876. When their approval was received, he began to prepare the famous Index Catalogue of the Surgeon General's Library, which, Edgar Erskine Hume<sup>1</sup> says, marked an epoch in the development of medical literature. Physicians who formerly

1. Hume, Edgar Erskine: *The Centennial of the World's Largest Medical Library: The Army Medical Library of Washington, Founded 1836*, M.H. Surgeon 78:241 (April) 1936.

obtained data and reviews in a haphazard way now have the literature of the world indexed in a convenient form. The first series of the Index Catalogue, comprising sixteen volumes, was published between 1880 and 1895; the second series, of twenty-one volumes, between 1896 and 1916, and the third series, of ten volumes, between 1918 and 1932. The first three volumes of the fourth series have more recently been published. The Index Catalogue is the most comprehensive bibliography ever attempted in any field. Its preparation, Sir William Osler said, is gargantuan. Dr. William H. Welch said that it is the greatest contribution of America to medicine.

John Shaw Billings had other talents. As Garrison shows in his memoir,<sup>2</sup> Billings designed the great Johns Hopkins Hospital in Baltimore. He was in charge of vital statistics during the tenth and eleventh census of the United States and was in part responsible for the development of the United States Public Health Service. He became professor of hygiene in the University of Pennsylvania; he consolidated and catalogued the three public libraries of New York City. He was the author of numerous publications, among which were<sup>3</sup> "A Sanitary Survey of the United States," "The Cholera Epidemic of 1873 in the United States," "Reports and Papers on the Johns Hopkins Hospital," "Reports on Barracks and Hospitals," "Reports on Diseases of Cattle in the United States," and his classic "Literature and Institutions." His greatest achievement, however, was the development of the Surgeon General's Library and the Index Catalogue. The development of student Billings into the great librarian makes it possible even today for physicians in any part of the United States to have access to much of the medical literature of the world, for on request through their local library they can borrow for a short time books and periodicals from the Army Medical Library in Washington, D. C.

### HOW TO REVIEW MEDICAL LITERATURE

The librarian of the New York Academy of Medicine, Dr. Archibald Malloch,<sup>1</sup> recently addressed the Hartford Medical Society at a dinner in honor of Dr. Walter R. Steiner, who for thirty-five years has been librarian of the society. Dr. Malloch said that physicians should be insured against certain risks which they may encounter after graduation: the risk of being satisfied with methods of diagnosis and treatment learned in medical schools; the risk of being content with what is good instead of

striving for what is better; the risk of intellectual or mental laziness which often comes to those in the midst of a busy practice; the risk of becoming rusty. The kinds of insurance against these dangers which the speaker suggested were: (1) the study of disease in private patients as well as in hospital practice and the recording of this experience in carefully taken notes; (2) discussion of problems at meetings of medical societies; (3) the publishing of brief papers about your cases; (4) the perusal of medical journals and books, so that it becomes a habit. "To study the phenomena of disease without books is to sail an uncharted sea, while to study books without patients is not to go to sea at all." These were the words of William Osler.

It is good for a physician to purchase a system of surgery and read some part of it every day; and, likewise, for a surgeon to read a system of medicine, making notes as he reads. The reading habit stimulated Bigelow to say that Oliver Wendell Holmes could get what he wanted out of a book as dexterously as a squirrel can take the kernel of a nut out of the shell.

Medical literature is indexed so well that work in the libraries is easier than if one were studying almost any other profession. The speaker did not refer to the very old bibliographies but mentioned first the *Index Medicus*, which was published in three series between 1879 and 1926, except that from 1900 to 1902 its place was taken by the *Parisian Bibliographica Medica*. In 1927 the *Index Medicus* joined with the *Quarterly Cumulative Index*, which had been published by the American Medical Association since 1916. The combined indexes were then published under the title *Quarterly Cumulative Index Medicus*, which continues to be published by the American Medical Association. You may readily see, Dr. Malloch said, that to find the articles and books which have been published on a subject, you would have to look in all the volumes of the *Index Medicus* and in all of the semiannual volumes of the *Quarterly Cumulative Index Medicus*. The great John Shaw Billings, the centennial of whose birth has been celebrated this year, was the father of the *Index Medicus*. He planned and brought out also a much more comprehensive work, the *Index Catalogue of the Surgeon General's Library*, which is still being published. The *Index Catalogue* began in 1880 and had passed through three series of volumes by 1932. The first volume of the fourth series appeared in 1936 and the second volume in 1937; the other volumes in the fourth series will appear from time to time. Each volume of the *Index Catalogue* covers all the medical literature in the Army Medical Library that is indexed under one or more letters of the alphabet, at the time of going to press. The *Index Catalogue* is an

2. Garrison, Fielding H.: John Shaw Billings: A Memoir, New York, G. P. Putnam's Sons, 1915.

3. Kiser, Edgar F.: John Shaw Billings of the Centenary of the Army Medical Library, J. Indiana M. A. 29:424 (Sept.) 1936.

1. Malloch, Archibald: A Short Talk on Medical Libraries, J. Connecticut M. Soc. 2:223 (May) 1938.

author and subject index in one alphabet, the books, reprints and theses appearing under "author," while under "subject" are found the books, theses and titles of all magazine articles. In the first series of the *Index Catalogue* was indexed all the old and new books in the Army Medical Library at the time, as well as all articles printed in old journals on down from the time of their beginnings. What a piece of work!

The second series of the *Index Catalogue* indexed the old or ancient books which had come to the library after the first series was published, and also old journal articles. The fourth series indexes under an author's name the old editions of his books that have been obtained since the corresponding volume of the third series was issued. Each volume of the *Index Catalogue* includes now about twenty years of modern literature. In attempting to find what has been written, for instance on the subject of pneumonia since the beginning of time, one has only to look at the volumes in the first, second and third series of the *Index Catalogue*, which list the publications on pneumonia, instead of looking at the many, many volumes of the *Index Medicus*. One should bear in mind, however, in connection with the third series of the *Index Catalogue* that in the volume Ge-Izzet Bey and later volumes no journal articles published after the end of 1925 were included. Articles not included in the third series will, however, be included in the volumes of the fourth series covering Ge to the end of the alphabet. For more recent articles on subjects not dealt with in the first two volumes of the fourth series of the *Index Catalogue*, one must consult the volumes of the *Quarterly Cumulative Index Medicus*.

Thus if one is writing a paper, the way to review the literature is to look at all titles of books and articles on one's subject listed in the volumes of the different series of the *Index Catalogue* and then go through all the volumes of the *Quarterly Cumulative Index Medicus*. What a historical perspective this will give! Do not let anyone look over these lists for you, Dr. Malloch advised, or you will miss much of great value. The greatest physicians that he has known have written their own papers, including the preparatory work. As you go through the lists, he continued, select the titles of monographs or articles that you wish to read. Look also at systems of medicine or surgery, for the titles of their articles are not given systematically in the published indexes. Should your library not possess all these books or journals, ask to borrow them from the Army Medical Library. Keep notes on little points that you desire to look up in the library. Visit the library regularly to see the new books and journals as they come in, and read what you wish of them. Browsing in libraries is a source

of great pleasure and profit. It was Osler's habit to go to the library of the Medical and Chirurgical Faculty of Maryland in Baltimore several times a week before dinner, and to make notes of what he read.

### THE SOCIAL SIDE OF MEDICAL PROGRESS

*Abridgement of an address before the annual meeting of the Minnesota State Medical Association, Duluth, June 30, 1938, by Dr. Howard W. Haggard of Yale University Medical School, New Haven, Conn., and published in Minnesota Medicine, October 1938.*

It is well at times to draw back a little from the details of immediate and practical projects and in contemplation to view medical and social situations in broad perspective, to see trends, directions and dimensions.

Viewed in this way the feature that shows as peculiar to the present period is the rapid shift and change of long established social institutions. As we watch these changes, the realization is forced on us that the body of society is a delicately integrated entity so interdependent in its parts that a change in any one must necessarily result in a change in all other parts, in a total readjustment.

Thus if medical discovery is made and applied to the saving of lives, there must follow a reorganization of society as a whole. The saving of life results in a change in the age structure of the population. The change in the age structure of the population upsets the balance of the established institutions and necessitates social and economic readjustments.

It is axiomatic in our field that, as one disease diminishes, others rise to take its place. As the incidence of tuberculosis, typhoid, dysentery and smallpox go down, cancer and diseases of the circulatory system rise correspondingly. The change in the leading causes of death in the last thirty-eight years is common-place knowledge.

Sometimes I think the physician fails to see that medicine itself is one of the institutions affected by the changes that are brought about. Medicine does not stand alone; it is an integral part of society. In the face of such change there appears one of the peculiarities of medicine: the failure to realize that it must change as society changes. The medicine of today may be vastly different from the medicine of the past but the fact remains that the social and sociological forces that guide it operate on it today just as they did in the past.

The great danger that I see to the practice of medicine today lies in the very thing that has given medicine its modern preeminence, and that is science. The physician has committed himself to science. He stands or falls with it. My indictment tonight is against this science—

a science that has led the doctor to neglect the equally fundamental and nonscientific social aspects of medical practice—those things that we sometimes sum up as the art of medicine, a thing about which the younger generation of physicians knows so little. The doctor, in making a fetish of science, may find himself worshipping alone. He will unless his medical practices are changed continually to suit precisely the society in which he lives.

The doctor of America in the eighteenth and early nineteenth centuries was not a scientist. He was a public-spirited man whose medicine suited the times. He was a social leader, embodying the rare combination of medical practice and sociology. We today look with pity, mingled with contempt, on the practices of Benjamin Rush. Yet, in spite of his lack of science, Rush as practitioner and medical leader has no equal today. The tenet of the young physician today is too apt to be the reverse of that of Rush.

The reason for the mode of thought that pervades medicine today is not hard to find. In the last hundred years, with the introduction of the exact sciences into medicine, medical research has yielded some of the most beneficial knowledge that the human race has ever acquired. Enthusiasm has grown high and a mode of thought crystallized. The science of medicine has been elevated; the practice of medicine, which is not a science and never will be, has been subordinated.

The emphasis on research has resulted in the development of an aura of sanctity about research. The acquisition of knowledge has received and still receives a cultivated regard amounting almost to a veneration, and one out of all proportion to the regard given to the application of the results of research. This mode of thought, scientific research—the search for novelty, the new—is inculcated in the medical student and hence in the physician; it has given a direction to medicine. And the movement has developed an inertia so that medicine cannot readily turn to new directions, although those directions are clearly indicated.

Medical science is not medical practice. The great benefits from the application of preventive medicine that so dominate the public mind today are not those of medical practice. These matters are science and being science they do not require the participation of the practitioner. Any aspect of medicine that has been reduced to an exact science needs merely medical technicians and not physicians for its accomplishment. Such is the case with much of our diagnostic tests. At one time it required the consummate skill of the physician to determine in some cases the presence of syphilis; now a far more accurate diagnosis is made by a

technician in the laboratory. When—and if—medicine becomes an exact science we shall no longer need the practicing physician. Until it does become an exact science, then we not only need him but we should grant him his due and proper importance.

#### THE ART OF THE PHYSICIAN

The practicing physician is not a scientist. He is, if he really practices medicine, more, far more, than a scientist. He is an artist. He does not deal with the controlled and limited matters of the laboratory; he deals with human beings. So long as the human mind in its full ramifications remains beyond an evaluation with scientific precision, then the practice of medicine must remain an art. So long as medical practice involves the personal contact of physician and patient, then it is the art of the physician which must establish the necessary bond. This is very different from medical research. It is, in many ways, more difficult. It involves not only intelligence and skill but also qualities of personality unnecessary to the research worker.

In the first flush of the triumphs of the application of science to medicine, it appeared that all the problems of medicine were to be answered and that medicine at last was destined to become as exact and impersonal as engineering. In consequence, to the eventual great detriment of the practice of medicine, our medical education was changed. It adopted the precise methods of science. It built its structure on the laboratory as a foundation.

#### MEDICAL EDUCATION

Let us trace the broad steps in the change in American medical education. A century and a quarter ago French medicine went through one of the periodic changes of direction. The old formal dogmatic teaching gave way to an active clinical investigative type of medicine. Germany, following the Napoleonic wars, was in the throes of a wave of idealism and romanticism that denied in the medical schools factual investigation and permitted only speculation. It was one of the extremes of the pendulum movement of education. Then it swung the other way; by the middle of the century German preclinical medicine had been founded by Johannes Müller. His pupils, including Virchow, give the roster of the famous teachers and investigators of Germany. Almost without exception, and this includes Müller, they were men with enormous social interests. Virchow, you will remember, was as fearless and fiery in his political activities and his denouncements as he was in the classroom. The best of German medicine was gradually brought to America. The part that caught and held attention was the research aspect. At first the leading schools in this country were

famous for their clinical teachers. The pre-eminence of Johns Hopkins in the closing years of the last century and the early years of this century was based on its great clinicians. Today, with the continual swing of the pendulum toward research, the preeminence of a school is judged not by how well it trains doctors for the practice of medicine but on the eminence of its researches. The chairs once occupied by great clinicians with wide social interests and wide social influences are too often filled by scientists out of touch with the real problems of the practitioner. Few great scientists have been eminent physicians. Formerly students in our schools were trained to be socially beneficial. Now they are trained too often with the apparent intention of making laboratory investigators out of them and that in spite of the fact that medical practice is a social application. Too often today we train not physicians with all the significance of the term but, instead, bedside pathologists.

Medical training is being divorced from medical practice; preclinical training is being sold out to educators who are not even physicians. The emphasis on science, on the laboratory, has extended down even into the premedical field in the college. The selection there is made on the basis not of socially minded individuals who would make good practitioners but of aptness in the laboratory subjects. The class of men who enter Eastern colleges are today, as potential material for social leadership, distinctly inferior to the young men from the same colleges entering law and business. We are turning away good men because no matter how great their ability might be as practitioners they show no aptitude for the technic of medical research.

#### SOCIALLY MINDED PHYSICIANS

There is a greater need for socially minded public-guiding physicians than at any previous period in medicine. The diseases that come to the front in the modern medical readjustment cannot be cured or prevented by impersonal science. They can be controlled only by the close and intelligent cooperation of the individual members of the public with the physician. Obtaining this cooperation is a vastly different matter from acquiring the knowledge of how to prevent or treat the disease. It is not medical research or science; it is the practice of medicine in its broadest service of a social leadership.

The social worker today knows that the greatest, indeed probably the only possible field of social betterment is offered by medical application. Some aggressive lay groups stand ready to raid the medical field for its unapplied potentialities. With the natural reaction of newcomers to the field, they assume there is something basically wrong with the form of

medical practice. Their first inclination is to remake the form of medicine.

Public opinion determines the condition and future of medicine. Advancement, construction, is not made by great numbers but by great individuals. It isn't what medicine does, it isn't what science discovers, that gives the necessary high public regard to the physician. It is what the public thinks and believes. The physician, in casting his lot with scientific research, stands and falls with it. And he has chosen an uncertain support. A social disturbance destroys first of all medical science. A little over a hundred years ago there was no medical science in Germany. Then in half a century Germany raised herself to world pre-eminence in medical science. And then in the present century, under changing social conditions, medical science declined in Germany; it is disappearing; it has already gone in Russia, Italy and Spain. We still have it, but it remains at the mercy of social change.

The permanent basis of medicine is not its research, but its social application—its practice.

#### APPLICANTS FOR ADMISSION TO MEDICAL COLLEGES

The study of applicants for admission to the freshman class of 1937 at seventy-eight medical colleges in the United States, published in the *Journal of the Association of American Medical Colleges*, is the tenth study of this kind made by Dr. Fred C. Zapffe,<sup>1</sup> secretary of that association. These annual studies provide reliable data on the number of applicants for admission to medical colleges, the action taken by the colleges, and the basis of acceptance and rejection. The number of applications for admission to the medical schools has increased from 29,705 in 1933 to 35,439 in 1936. The number of applicants accepted, however, has steadily declined from 7,419 in 1934 to 6,410 in 1937. Nearly 11 per cent of accepted applicants in 1937 did not enroll.

The 1937 freshman class was the smallest in ten years. The agreement between the Council on Medical Education and Hospitals of the American Medical Association and the Association of American Medical Colleges that there should be one full-time teacher for each twenty-five students in the preclinical departments has tended to make smaller classes. When general business conditions are good, attendance in medical colleges falls off, and vice versa; the attendance reached a record high in 1932 and has since declined. From 23 to 25 per cent of students entering will not graduate. About 200 repeaters enter every freshman class, 75 per cent of whom fail to make good.

1. Abstract of a paper by Fred C. Zapffe, published in the *Journal of the Association of American Medical Colleges*, May 1938.

Women multiple applicants have increased at a greater rate than men; there were 60 per cent more women multiples in 1937 than in 1933. Otherwise the number of women applicants has followed the same trend as that of the men applicants. Sixty-two per cent of women applicants were accepted in 1933, 52.4 per cent in 1937 (52.5 per cent of men were accepted in the same year). The total of accepted women applicants remains under 400 each year.

The number of medical students who have had less than three years of college work is decreasing each year. Accepted applicants of this group constitute 9.2 per cent of all accepted applicants. Of all applicants, 32.6 per cent have had three years or more of college (no degree) and 54.7 per cent of this group were accepted. The degree group represented 52.1 per cent of all applicants; 55 per cent of this group were accepted. Applicants are not discriminated against on the basis of college work taken, if the scholastic record is good.

Data are submitted on the total number of applications made in 1937 to seventy-eight

medical schools. Five schools (Columbia, Northwestern, Pennsylvania, St. Louis and Temple) had more than 1,000 applications each. The maximum was 1,263 (Pennsylvania). These schools and twelve others enrolled more than 100 students each. Nine schools (including six two-year schools) had less than 100 applications. Thirty of the schools enrolled less than sixty students each.

In 1937, data on 5,643 multiple applicants show how they fared as to acceptance. The group has increased 22 per cent since 1933 but acceptance of multiples has declined 11 per cent in five years. Single applicants have diminished 10 per cent in five years. Thirty-two per cent of multiples made two applications, about 40 per cent made from three to five applications, about 18 per cent from six to ten applications, about 8 per cent from ten to twenty applications and the remainder more than twenty applications. Many multiples continue to make applications for years with no acceptances; one person made seventy applications in three years.

## Medical College News

*Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section.*

### Stanford Students Active in November Election

The student body of Stanford University School of Medicine, San Francisco, took an active part in the November 8 election with regard to State Proposition No. 2 on the ballot, which was said to be misnamed the "Humane Pound Act." The student body said "it is a vicious threat to the health and well-being of the public, camouflaging regulations of animal pounds." It proposed to prohibit the use of animals by universities, medical schools and laboratories for scientific purposes. The proponents of this bill, the student body said, "show an utter disregard for the invaluable knowledge with which biologic research has equipped the physician to battle disease." As future physicians charged with the responsibility of the maintenance of health and the prevention and cure of disease, the student body urged the defeat of the so-called Humane Pound Act. The California voters defeated the proposal.

### Larger Quarters for Interns

Two additional floors on the Administration Building of the University Hospital, Ann Arbor, Mich., are to be constructed to provide for the housing of the entire intern staff within the main hospital building. In addition to sleeping quarters there will be recreation rooms and lounges for the interns and hospital staff. The two houses which now are occupied by some of the interns will be released for other purposes.

### American Student Health Association

The annual meeting of the American Student Health Association will be held December 29-30 at the Hotel New Yorker, New York City.

### Fellowships in Anesthesiology

Graduate fellowships in anesthesiology have been established by the Medical School and Graduate School of the University of Minnesota, Minneapolis, for physicians who desire to prepare themselves for the practice of this specialty. The fellowships offer an abundance of clinical training in all types of local, regional and general anesthesia and gas therapy, and also adequate related graduate work in chemistry, anatomy, physiology and pharmacology. Applicants must have served at least one year in a rotating internship.

### Iowa Promotions

Dr. Ewen M. MacEwen, dean, State University of Iowa College of Medicine, Iowa City, announces the following promotions on the faculty:

Harry M. Hines, Ph.D., associate professor to professor of physiology.

Waid W. Tuttle, Ph.D., associate professor to professor of physiology.

Dr. William F. Mengert, assistant professor to associate professor of obstetrics and gynecology.

Dr. John H. Randall, assistant professor to associate professor of obstetrics and gynecology.

Dr. Emory D. Warner, assistant professor to associate professor of pathology.

Dr. Thomas L. Waring to assistant professor of orthopedic surgery.

Dr. James A. Greene, assistant professor to associate professor of theory and practice of medicine.

### Michigan Personals

Marshall L. Snyder, Ph.D., teaching assistant in bacteriology at the University of Michigan Medical School, Ann Arbor, has been appointed instructor in bacteriology. Vivian G. Behrmann, M.S., assistant in physiology at the University of Michigan Medical School, has resigned to accept an appointment in the Woman's Medical College of Pennsylvania, Philadelphia.

### New Teachers at University of Tennessee

The following appointments to the faculty of the University of Tennessee Medical School, Memphis, have been announced:

Dr. Kendall B. Corbin, formerly of Stanford University, Calif., to be associate professor of anatomy.

Frank Harrison, M.S., formerly of Northwestern University School of Medicine, Chicago; instructor in anatomy.

Howard C. Peters, Ph.D., formerly of the University of Minnesota Medical School, Minneapolis; instructor in physiology.

Dr. Robert A. Bussabarger, formerly of Detroit; instructor in pharmacology.

Charles C. Rainey, Ph.D., formerly of Berry College, Mount Berry, Ga.; instructor in chemistry.

### Four Year Course in Preventive Medicine

A grant of \$84,000 from the Commonwealth Fund has been made possible at New York University College of Medicine, New York, for a new program on preventive medicine which will comprise studies covering a four year period. In the announcement the dean, Dr. Currier McEwen, is reported to have said that the nucleus of the new department of preventive medicine was the Hermann M. Biggs professorship in preventive medicine, established years ago as a memorial to the late Dr. Biggs, who was a pioneer in public health work. The expansion of the department at this time is in recognition of the work of the late Dr. John Wyckoff. Dr. Harry Stoll Mustard will be director of the department and the program will be conducted by a full time staff of instructors and technicians. Instead of concentrating studies in preventive medicine in the last two years of regular medical college work, it will now begin in the freshman year. A teaching and research center will be provided in the facilities of the lower East Side Health District, the use of which has been made possible through the cooperation of the New York City department of health.

### Maryland Personal

Dr. Charles D. Smith has resigned as chief resident of the Radiological Department of Johns Hopkins University School of Medicine, Baltimore, and has entered private practice at Richmond, Va.

### Wayne University News

A total of \$45,000 has been accepted by the Wayne University College of Medicine, Detroit, in support of research and teaching at the college of medicine. The largest single gift was \$10,000 for the establishment of a research laboratory in ophthalmology. Dr. Parker Heath, professor of ophthalmology, has charge of the laboratory. Gordon L. Walls, Sc.D., has been appointed research associate in ophthalmology.

### Texas Personals

Drs. Isaac P. Barrett and Harold M. Williams, Fort Worth, assistant city health director and city epidemiologist, respectively, have been awarded scholarships for public health studies at Vanderbilt University, Nashville, Tenn.

### Three Generations of Doctors

With the graduation of Drs. James B. Witherington and Albert S. Witherington, Millington, in September from the University of Tennessee School of Medicine, Memphis, there have been three successive generations of physicians in the Witherington family. Dr. Albert S. Witherington Sr., Millington, graduated from the Memphis Hospital Medical College in 1904 and his father, Dr. James B. Witherington, Munford, from Vanderbilt University School of Medicine, Nashville, in 1878.

### Six Surgeon Generals from University of Pennsylvania

The University of Pennsylvania School of Medicine, Philadelphia, is credited in the October *Pennsylvania Gazette* with having graduated six surgeon generals of the United States Army Medical Corps. They were Clement A. Finley, who graduated in 1818 and served as surgeon general from May 15, 1861, to April 14, 1862; Joseph K. Barnes, who graduated in 1838 and served as surgeon general from Aug. 22, 1864, to June 30, 1882; Robert Murray, who graduated in 1843 and served as surgeon general from Nov. 23, 1883, to Aug. 6, 1886; William H. Forwood, who graduated in 1861 and served as surgeon general from June 8, 1902, to Sept. 7, 1902; Robert M. O'Reilly, who graduated in 1866 and served as surgeon general from Sept. 7, 1902, to Jan. 14, 1909, and the present surgeon general, Charles R. Reynolds, who graduated from the University of Pennsylvania in 1899 and was appointed surgeon general in 1935, after many years of distinguished army service.

### Faculty Changes at Columbia

The following medical appointments and advancements at Columbia University, New York, have been announced:

Associate Professor, Dr. Milton Carl Peterson (New York Post-Graduate Medical School).

Assistant Professors: Dr. Virginia Apgar, anesthesia; Dr. Gaston Arthur Carlucci, clinical surgery; Dr. Beatrice Maher Kesten, clinical dermatology; Dr. Rafael Rodriguez-Molina, tropical medicine (School of Tropical Medicine); Dr. Jose Rodriguez Pastor, bacteriology and hygiene (School of Tropical Medicine); Dr. Otto Klineberg, psychology; Clarence R. Carpenter, Ph.D., anatomy.

Assistant Clinical Professors: Drs. Abbott William Allen, medicine (New York Post-Graduate Medical School); Zacharias Berco-vitz, medicine (New York Post-Graduate Medical School); John Dorsey Craig, pediatrics (New York Post-Graduate Medical School); John Staige Davis Jr., medicine (New York Post-Graduate Medical School); Frank Miller Falconer, medicine; Julian Maxwell Freston, medicine; Samuel Waldron Lambert Jr., medicine; Robert McGrath, medicine (New York Post-Graduate Medical School); Thomas Turlay Mackie, medicine; Theodore Neustaedter, gynecology (New York Post-Graduate Medical School); Robert Louis Preston, orthopedic surgery (New York Post-Graduate Medical School); Theodore Campbell Thompson, orthopedic surgery.

### New York Personal

Dr. Ralph E. Knutti, assistant professor of pathology at the University of Rochester School of Medicine, New York, addressed the students and faculty of the West Virginia University School of Medicine, Morgantown, September 23, on "Plasma Protein Regeneration."

### Appointments at Duke University

The following appointments were made recently to the faculty of the Duke University School of Medicine, Durham, N. C.: Dr. Harold W. Brown, professor of preventive medicine and public health; Dr. James P. Hendrix, associate in medicine, and Hans Neurath, associate in biochemistry.

### South Carolina Personal

Dr. S. C. Werch, demonstrator in physiology at the School of Physic, Trinity College, Dublin, has been appointed instructor in the department of pharmacology in the Medical College of the State of South Carolina.

### Fordham Opens New Pharmacology Laboratory

Fordham University, New York, has opened a newly equipped laboratory for applied physiology and pharmacology in the Pharmacy Building on the campus, in conjunction with the inauguration of a new course leading to the degree of Bachelor of Science in Pharmacy. The laboratory will be used

for the new courses in physiology and pharmacology for the sophomore and junior students in B.S. courses in pharmacy and for graduate students who wish to further their studies. It is fully equipped for research, and apparatus for the study of body function and drug action is available for student use. The laboratory will be under the direction of Leonard J. Piccoli, Ph.D., professor of materia medica, pharmacology and physiology. Its facilities will also be used by the seniors and graduate students of biochemistry who are taking courses in anatomy and physiology under Dr. Piccoli.

#### Wisconsin Personal

Malcolm R. Irwin, Ph.D., associate professor of genetics, University of Wisconsin, Madison, addressed the university medical society October 27 on "The Inheritance of Resistance to Bacterial Infection."

#### Changes at the University of Texas

The board of regents has approved the following appointments to the faculty of the medical branch of the University of Texas, Galveston:

Dr. John L. Otto to the department of neurology, replacing Dr. Martin L. Towler, resigned.

Dr. James H. Herrod to the department of obstetrics, replacing Dr. Charles M. Mulherin, resigned.

Drs. Elva A. Wright, Fred B. Smith, Frank J. Hams and Adair W. White, staff members of Jefferson Davis Hospital, Houston, who will serve without pay in the department of obstetrics.

Dr. Wylie F. Creel to the practice of medicine department, replacing Dr. Michael B. Shimkin, resigned.

Dr. Robert A. Edwards as graduate assistant in the practice of medicine.

Dr. Charles E. Webb assistant in surgery, Dr. Clyde E. Thomas Jr. junior assistant in surgery, and C. C. Scott assistant in physiology.

#### Tennessee Personal

Cleveland S. Simkins, Ph.D., associate professor of anatomy, University of Tennessee College of Medicine, Memphis, has resigned to become head of the department of anatomy at Creighton University School of Medicine, Omaha, effective September 15. After receiving the degree of doctor of philosophy at Harvard University in 1921, Dr. Simkins was appointed assistant professor of histology at the University of Tennessee. He was appointed associate professor of anatomy in 1923.

#### Iowa Personal

Dr. Raymond G. E. Bunge, of Imlay City, Mich., has been appointed to the staff of the department of urology, University Hospital, at the University of Iowa, Iowa City. Dr. Bunge interned two years at the University Hospital at Ann Arbor, Mich., after receiving his M.D. in 1936 from the University of Michigan.

#### New Pathology Building at Georgia

The construction of a new laboratory and classroom building to house the departments of pathology and bacteriology at the University of Georgia School of Medicine, Augusta, was begun September 28. The new building will be adjacent to the Dugas Building, which also is new, and the cost of construction will be \$70,000.

#### District of Columbia Personal

Dr. Walter Andrew Bloedorn, professor of medicine in the School of Medicine of the George Washington University, Washington, D. C., and medical director of the University Hospital, has been appointed acting dean of the school of medicine.

#### Michigan Awards the Sternberg Medal

The Sternberg Memorial Medal, which was established in honor of the late Dr. George M. Sternberg, formerly surgeon general of the United States Army, is awarded annually to the medical student who has made the best record in preventive medicine. The award is made by the faculty on the recommendation of a committee. The winner in 1938 was Dr. William Kaufman.

#### Kentucky Personals

Dr. Jackson M. Thomas has resigned his position as associate professor of psychiatry at the University of Louisville School of Medicine to enter the department of psychiatry at Harvard University, Boston. Dr. William K. Keller has been appointed to fill the vacancy. Dr. Keller, a native of Louisville, recently completed a year of study in London on a Rockefeller fellowship.

#### Scholarships and Fellowships at Harvard

Harvard University Medical School, Boston, has awarded sixty-three scholarships totaling \$25,578 to medical students and has also awarded twenty-four fellowships totaling \$21,650 for the coming academic year. The names of the fellowships together with the recipients and the departments in which they work are given in the following list:

Edward Austin Fund Teaching Fellowships: Oliver H. Lowry, biochemistry; Duncan E. Reid, obstetrics; Bernard R. Hodes, physiology; James M. Parker, surgery.

Edward Hickling Bradford Fellowship for research: Francis S. Cheever, bacteriology.

John White Browne Scholarship for research: Smith Owen Dexter Jr., medicine.

William Story Bullard Fellowships for research: Arnold Max Seligman, chemistry; Bernard David Davis, physical chemistry; Lawrence C. Kingsland Jr., medicine.

Arthur Tracy Cabot Fellowship for advancement of surgery: John E. Dunphy, surgery.

James Jackson Cabot Fellowship "to aid and encourage practical work in scientific medicine": John Holmes Dingle, surgery.

DeLamar Student Research Fund: Bernard German, bacteriology; Nathan B. Kurnick, physiology; Stanley M. Levenson, public health; Edward Meilman, biochemistry; John Holmes Dingle, surgery.

Louis E. Kirstein Fellowship: Louis H. Nason, surgery.

William O. Moseley Jr. traveling fellowship for study in Europe: Dale Gilbert Friend, biochemistry; Rolf Lium, surgery; John Burton Dynes, psychiatry.

Francis Weld Peabody Memorial Fellowship for intensive clinical and laboratory studies: Arnold P. Meiklejohn, medicine.

Jeffrey Richardson Fellowship for continuation of studies either here or abroad: Lewis Dexter, medicine.

The Whitman Fund, for pursuing the study of medicine or surgery at the Ecole de médecine de Paris: John Burton Dynes, psychiatry.

Dr. William Hunter Workman Scholarship to enable graduates of Harvard Medical School to pursue postgraduate studies in medicine in this country or abroad: Robert P. Tucker, biochemistry.

#### North Dakota Personal

Dr. Russell A. Nelson, Minot, N. D., a graduate of Johns Hopkins University School of Medicine in 1937, has been appointed assistant resident physician at Johns Hopkins Hospital, Baltimore, and assistant instructor in medicine at Johns Hopkins University.

#### The Holden Trust Fund at Western Reserve University

Western Reserve University, Cleveland, came into possession of the principal of the Albert Fairchild Holden Trust Fund August 25, which was the twenty-fifth anniversary of the death of Liberty E. Holden, who established the foundation as a memorial to his son. The fund, which is said to be worth at least a million and a half dollars, will continue to be used, as directed by Mr. Holden, for lectures and research in the School of Medicine.

## THE MEDICAL MANAGEMENT OF CHRONIC ULCERATIVE COLITIS

THOMAS T. MACKIE, M.D.

Assistant Clinical Professor of Medicine, Columbia University,  
Attending Physician, the Roosevelt Hospital  
NEW YORK

Chronic ulcerative colitis remains one of the most controversial problems in the field of disorders of the gastrointestinal tract. Opinion is divided with respect to classification. There is marked divergence of opinion concerning the natural history of the disease and its prognosis. There is no agreement concerning etiology, and no uniformity in the various philosophies of treatment.

It is apparent from the literature that the criteria for classification must be altered. There has been and still is a school of thought which regards the associated bacterial flora as the fundamental index rather than the anatomic and physiologic changes which the disease produces. Thus, by the operation of such a system of nomenclature, the isolation of *Shigella dysenteriae* in a case presenting chronic inflammatory lesions of the colon automatically excludes the case from the group styled chronic ulcerative colitis. Such arbitrary subdivision is made without respect to the pathology, physiology or natural history of the disease. Two evils result: There is constant pressure to restrict rather than to broaden the scope of investigation. The inevitable confusion of thought leaves the clinician hopelessly lost in a sea of argument at cross purposes.

Morbid anatomy constitutes the proper basis for classification. The fundamental pathologic condition of chronic ulcerative colitis may be defined as the sum of necrosis plus productive inflammation. This creates the varied pictures seen under the microscope and in gross specimens. There is diffuse destruction of normal tissues, inflammation accompanied by hemorrhage and intense polymorphonuclear infiltration, fibroblastic proliferation and later formation of dense and extensive collagenous scar tissue. Recognition of these changes automatically excludes from consideration conditions such as amebiasis, tuberculosis and syphilis, which present characteristic and distinctive pathologic pictures.

Differing hypotheses have been advanced to account for the development and progression of these lesions. The concept of infection is widely held. A variety of micro-organisms have been proposed as the primary agents.

Hurst<sup>1</sup> has long considered the disease to be the result of continued infection by *Shigella dysenteriae*. The proponents of this hypothesis base their views largely on the results of the agglutination reaction. Dysentery agglutinins, however, are frequently present in the absence of demonstrable homologous infection.<sup>2</sup> Furthermore, there is evidence to indicate that these antibodies appear in response to heterologous infection by certain strains of *Escherichia coli*.<sup>3</sup> Dysentery bacilli have been isolated in approximately 20 per cent of the cases that I have seen in New York City.<sup>4</sup>

Bargen<sup>5</sup> and his associates hold that a specific diplococcus is responsible and that this organism can be recovered in 80 per cent of the cases.<sup>6</sup> The specificity of this organism has been denied. Strains obtained from the Mayo Clinic have been shown to differ among themselves in their behavior in culture and in heat resistance. Their serologic characteristics are not uniform and there is close immunologic relationship with strains of *Enterococcus*.<sup>7</sup> Other investigators have failed to recover the diplococci in a large proportion of their cases.<sup>8</sup>

More recently an anaerobic bacterium has been advanced as the primary agent.<sup>9</sup> In like fashion most of the bacteria recoverable from the human colon have, at one time or another, been suggested as important etiologic factors.

Andresen<sup>10</sup> first reported that food allergy plays a definite role in certain cases of chronic ulcerative colitis. The clinical evidence on which this conclusion was based is supported by experimental data. Allergy is characterized by sensitization and immunity, which may develop separately. Sensitization followed by exposure to the specific antigen produces allergic inflammation which may be accompanied by actual necrosis of tissue. Inflammation is known to favor local fixation of anti-

gen.<sup>11</sup> Following such fixation, subcutaneous, intravenous or intragastric administration of the homologous antigen is followed by an acute inflammatory reaction.<sup>12</sup> Moreover, passive local sensitization of the gastrointestinal tract in experimental animals and of the rectum in man<sup>13</sup> indicates that the colon may properly be classed as a shock organ.

Another school of thought holds that a large proportion of the cases are of psychogenic origin.<sup>14</sup> Emotional disturbances operating through the vegetative nervous

system are believed to produce hyperperistalsis and surface digestion of the mucosa of the colon.

Studies previously reported<sup>15</sup> have led to the belief that conditioned deficiency disease constitutes an important secondary factor in the mechanism of many cases of chronic ulcerative colitis.

It is inevitable that these differing concepts should lead to a variety of different forms of therapy. These have been principally directed to the effort to eliminate infection. Vaccines of various types, antisera, bacteriophage, irrigation with many types of antiseptic solutions, irradiated oils, irradiated transfusions and the exhibition of adsorptive agents such as fullers' earth and bismuth all have had their enthusiastic proponents. The antibacterial approach to the problem has even determined the time for surgical intervention and the procedure to be performed. Appendicostomy, cecostomy and colostomy have been carried out many times in the belief that by facilitating through and through irrigation cure might be obtained.

Proximal to sigmoid only.....	2

The same conflict of opinion exists with respect to prognosis. For example, Hurst<sup>16</sup> believes that a large majority of patients irrespective of the severity of the disease may ultimately lead a life of normal activity

free from recurrences. Paulson,<sup>17</sup> on the other hand, considers permanent cure only a remote possibility in all but the exceptional cases. Frequently statements of results of therapy are based on relatively brief periods of observation and subsequent reports of the subjective phenomena noted by the patient. Despite the optimistic statements there is a deeply rooted belief in the profession that therapy is inefficient and that ulcerative colitis, once established, becomes a chronic disease exhibiting recurring periods of activity and quiescence.

The studies here reported were undertaken in the belief that continuous investigation of a group of cases over a prolonged period might yield information of value.

## METHODS

Proctoscopy was done on each patient at every visit, and cultures were taken directly from the rectal or rectosigmoidal mucosa on plates of MacConkey agar, eosin-methylene blue agar and desoxycholate agar. From slightly more than half of the patients tall tubes of Rosenow's glucose brain broth have been inoculated and studied by the Bagen technic.<sup>18</sup> Recently anaerobic cultures have been made from a small proportion of the group.

The distribution of the lesions has been determined by means of the sigmoidoscope and a barium sulfate enema. Motor physiology of the intestine has been

Anacidity.....	12

studied by twenty-four and forty-eight hour x-ray films of the abdomen after oral administration of the barium compound. During the test period the patients receive the usual dietary, but cathartics and sedatives are withheld.

Fractional gastric analyses have been performed with histamine stimulation.

Allergic studies were done by the test diet method and the repeated addition and withdrawal of suspected foods.

Owing to financial obstacles and difficulties of cooperation, it has not been possible to make complete observations in all cases of the group.

## MATERIAL

Eighty-five cases of chronic ulcerative colitis have been studied for periods varying from eighteen months to six and a half years. All but twelve have been followed for two years or more. Fifty-one have been studied for three years or more. These patients have been drawn from dispensary, hospital and private practice in New York City. They constitute a selected group in the sense that only those cases frequently examined throughout the period of observation and only those studied for a minimal period of eighteen months are included.

The extent of the pathologic condition in the colon as shown by proctoscopy and x-ray examination was

determined in eighty-five cases. The entire colon from the cecum to the rectum was affected in twenty-six. Involvement distal to the splenic flexure and distal to the sigmoid comprises the next largest groups. In two cases the lesions were limited to that portion of the colon proximal to the sigmoid flexure.

Fractional gastric analysis with histamine stimulation was performed in seventy-two patients. Disturbances of gastric secretion were found to be not uncommon, particularly in the severe cases. Anacidity was present in twelve and hypoacidity in twenty-two.

TABLE 4.—Colon Motor Rate (Forty-Two Cases)

	Cases
Normal motor rate.....	10
Hypermotility.....	11
Hypomotility.....	21

The profuse diarrhea and pain so common in the severe case is attributed to hyperperistalsis and hypermotility of the intestinal tract. This is by no means always the fact. Twenty-one of the forty-two cases examined revealed hypomotility in association with frequent evacuations, abdominal cramps and tenesmus. In these instances there is definite and often prolonged delay of forward progress of the barium in the proximal half of the colon. Occasionally I have observed this delay to extend over ninety-six hours. Thus there may exist the paradox of marked constipation accompanying what seems to be a profuse diarrhea. The exhibition of sedatives and antispasmodics in such a situation merely aggravates an already abnormal condition. Hypermotility, with complete evacuation of the barium sulfate meal in twenty-four hours, occurs less often. The importance of determining which of these two mechanisms is operative in a given case is self evident. Further reference will be made to this in the discussion of therapy.

The bacteriologic studies have not revealed a high incidence of any recognized single pathogenic organism. The flora varies greatly from case to case and in the same case at repeated observations. Unidentified strains of Salmonella have been recovered in many instances. Their pathogenicity has not been investigated. Strains of Shigella dysenteriae have been isolated in twenty-one of the group. The Morgan bacillus No. 1 is likewise not uncommon, and beta hemolytic streptococci have been recovered in certain of the cases.

Recently the bacteriologic investigations have been amplified to include routine use of the Rosenow glucose brain broth with the technic prescribed by Bargen. Forty-seven cases have been studied. Gram-positive diplococci have been recovered from thirty-five. None of these conformed to the cultural criteria and heat resistance test described as characteristic of the "diplococcus of ulcerative colitis." Only one strain conformed to a type strain originally obtained from the Mayo Clinic. It did not agree, however, with two other type strains obtained from the same source.

The sugar fermentations, heat resistance and morphology observed in the diplococci that I have recovered permit their classification only as members of the Streptococcus faecalis group.

Anaerobic cultures have only rarely yielded Bacterium necrophorum.

Prolonged study of these cases has repeatedly demonstrated that a factor of allergy participates in the mechanism of many cases of chronic ulcerative colitis. The frequent association of infection of the upper respiratory tract with recurrence of activity of the disease or with increased severity is well known. On several occasions I have had the misfortune to witness a sudden increase in severity following immediately on an overdose of autogenous vaccine which produced marked local and systemic reaction. Particular foods likewise frequently play a similar role.

The recognition of food allergy in these cases necessitates use of the test diet method of study. Cutaneous tests yield misleading information. Both false positive and false negative reactions are obtained. It is frequently necessary to repeat the test diet studies in order to demonstrate the mechanism in a given patient. Negative results at one time may give way to clearcut and predictable response to the successive exhibition and withdrawal of a particular food a few weeks or months later. The reactivity of the colon therefore exhibits a phasic variation in this respect, apparently corresponding to successive periods of sensitization and desensitization. In some instances evidence of food allergy is obtainable during periods of activity of the disease. In others this factor is demonstrable only in the early stages of recurrence. The following case abstracts illustrate these points:

CASE 77.—The patient, first seen in January 1935, gave a history of continuous diarrhea with bloody mucus and pus since the autumn of 1930. A variety of methods of treatment had been used with little or no improvement.

At the time she came under my observation she was having from four to six liquid stools a day containing considerable amounts of blood and mucus. There was obvious loss of weight and moderate anemia. Proctoscopic examination revealed a diffusely inflamed, thickened, pitted and bleeding mucous membrane extending to the limit of visualization in the rectosigmoid.

A barium sulfate enema showed no evidence of pathologic change proximal to the sigmoid. Cultures from the rectal mucosa yielded large numbers of beta hemolytic streptococci. These were not present in the pharynx.

No history of allergic disease or known food sensitization could be obtained from the patient or her family. Intracutaneous tests with many antigens gave negative results except to coffee, tea, pea, carrot, apple and goat.

Autogenous vaccine failed to produce either subjective or objective improvement.

A milk-free diet was started February 8, with prompt subjective improvement. Stools were reduced in number, mucus was much diminished and bleeding practically ceased. By March 7 the stools had dropped to an average of from two to four in twenty-four hours. Blood and mucus were absent except on two occasions immediately after she had taken orange

juice, which was then omitted. Proctoscopic examination revealed a much less acutely inflamed mucosa which did not bleed.

Milk and milk products were added to the diet at this time. Forty-eight hours later considerable amounts of mucus and blood reappeared and continued for two days after the milk-free diet was resumed. This was continued. By June 25 the patient was symptomatically well and proctoscopic examination revealed a mucosa which was normal save for slight thickening and scarring.

CASE 71.—The patient was first seen in May 1936 when he was seriously ill in the hospital. A positive family history of allergy was obtained. Proctoscopic examination revealed a characteristic picture, and a barium sulfate enema demonstrated an advanced ulcerative colitis extending from the hepatic flexure to the rectum. For two and a half months his condition remained precarious. A moderately severe deficiency disease complicated management. Test diets gave negative results. Finally forced feeding by gavage was resorted to, a synthetic diet containing milk and eggs being used. He was discharged from the hospital August 28 on a general diet, in excellent condition and averaging from two to three stools each twenty-four hours.

October 9 he reported that milk, orange juice and spinach caused increased looseness of the stools. This observation was confirmed by test diets, and the offending foods were omitted.

During the autumn of 1936 he remained in good condition. Proctoscopic examination revealed scattered small follicular

Secondary or conditioned deficiency disease has occurred as a complicating factor in forty-six of the cases. It appears to be the expression of the combined deficit of a number of essential factors. Lowering of the plasma proteins and inversion of the albumin-globulin ratio is not uncommon. The blood calcium is frequently below normal levels. The vitamin A and vitamin C values are often low, and it is probable that certain of the other vitamins are similarly affected.

These mixed deficiency states appear insidiously and gradually assume increasing significance. They may play a most important role in the course of the disease and in the more severe cases may determine the outcome. Recognition of this complication and intensive therapy is essential. The following case illustrates certain of these problems:

CASE 67.—The patient was admitted to the hospital in February 1936 with a history of recurrent attacks of colitis since 1929. In the autumn of 1935 a severe and progressive recurrence developed. During the three weeks prior to admission she had been on a diet low in vitamin C. At the end of this period a series of massive intestinal hemorrhages occurred and the red blood cell count fell to two million. The temperature was elevated and septic. The skin was dry and harsh, and the tongue was beefy red. The abdomen was markedly distended and tender on palpation. There was constant severe abdominal pain. The stools varied from twenty to thirty in twenty-four hours, many of them passed involuntarily, and they contained large amounts of mucus and blood.

The diet was modified immediately and supplemented by 250 mg. of crystalline vitamin C intravenously each day. Determination of vitamin C in the blood and urine unfortunately could not be carried out. Critical cessation of bleeding occurred at the end of the first week. During the ensuing weeks extreme anorexia constituted the major problem and undoubtedly was an important contribution to the subsequent developments.

The anemia was treated at first by three transfusions and then by iron, which brought about satisfactory blood regeneration up to the first week of March.

At this time the tongue became acutely inflamed, serpiginous ulcers covered with grayish slough appeared, and there were numerous aphthous ulcers in the buccal mucosa. The sloughs on the tongue separated after a few days, leaving a smooth, inflamed surface. At this time a symmetrically disposed eczematoid rash appeared on the lower part of the thighs, the anterior aspect of the knees and over the lower legs. She became markedly edematous, and free fluid was present in the abdominal cavity. The anemia became macrocytic, response to iron ceased and megaloblasts were present in the stained blood films.

Gavage feeding of a synthetic diet high in protein and vitamins was instituted. Large daily doses of unconcentrated liver extract (Lilly) were given parenterally.

The anemia and the lesions on the tongue, mouth and skin responded promptly. The subsequent course was uneventful and the patient was discharged from the hospital April 18.

# COMMENT

These observations have led me to certain conclusions concerning the mechanism of chronic ulcerative colitis. The evidence so far available does not justify the hypothesis that the disease is a specific infection resulting from the primary action of a single specific micro-organism. On the contrary, there is much evidence to indicate that it may be initiated by any one of a number of bacteria, known to be pathogenic and known to produce inflammatory lesions in the colon. Once the mucosal barrier has been broken by such an agent, secondary infection necessarily occurs. The secondary invaders will naturally include certain of the bacteria present in the colonic contents. Sections of colon removed surgically or at autopsy and stained for

ulcers and a hyperemic mucosa. From October through December *Shigella dysenteriae* Flexner was isolated on six occasions in almost pure culture.

An acute recurrence of active colitis developed in January 1937 after administration of autogenous Flexner bacillus vaccine. The patient was again hospitalized for twelve weeks. Milk, wheat, egg and spinach seemed definitely to increase symptoms at this time. Definite improvement occurred on the test diets. He was discharged in April and, contrary to advice, resumed the ingestion of milk, which he tolerated without apparent difficulty until August, when the stools increased in number and became looser, and mucus and blood reappeared. Immediate improvement occurred following the withdrawal of milk and milk products from the diet, even though the patient strenuously objected to this measure.

These two cases illustrate the varying response to dietary study in the different phases of the disease. The second case emphasizes the necessity for repeated search for a possible factor of food sensitization.

Satisfactory allergic studies were completed in sixty-seven cases. Classification was based on the subjective phenomena reported by the patient and more particularly on the appearance of the mucous membrane of the rectum and the rectosigmoid at repeated proctoscopic examination after each change in diet. Clinical evidence of active food allergy was obtained in forty-four cases. In seven others the evidence was equivocal. A history of allergic disease in the patient or in the patient's family was not a common finding. Idiosyncrasies to certain foods have been noted by about half of the cases. In the order of frequency, the foods most commonly at fault were milk, egg, orange, wheat, spinach and tomato.

bacteria reveal gram-negative bacteria in the more superficial portions of the affected tissue and gram-positive organisms in the deeper levels. Under such conditions it is not remarkable that conflicting observations have been recorded, nor is it remarkable that special methods will yield certain types of bacteria in significant numbers. Both types of observation are factual. Unfortunately they have tended to create dis-sension rather than progress.

The phenomena of the disease appear to result from the combined action of a number of factors. There is infection, probably always mixed in character, of the affected portion of the wall of the colon. Both the secretory and the motor physiology of the gastrointestinal tract are adversely and variously affected. Sensitization of the colon to foreign protein of bacterial and dietary origin plays an important role in the mechanism of relapse and activity of the disease. Not infrequently secondary deficiency states occur and assume major clinical importance.

#### TREATMENT

The medical management of chronic ulcerative colitis must be based on this complex mechanism and it must be guided by the phenomena observed in the particular case. In the past the greatest emphasis has been placed on antibacterial measures. This originated in the concept that ulcerative colitis is a simple infection and that its effects, both pathologic and physiologic, are restricted to the colon. This hypothesis is no longer tenable. The great variety of antibacterial measures advocated bears mute but impressive testimony to the inadequacy of all.

Disturbances of normal physiology must be compensated. Hydrochloric acid in amounts up to 4 cc. with meals is of definite value in the presence of anacidity. It tends to control distention and flatulence and to curtail the diarrhea. Sedatives such as phenobarbital and at times opium derivatives are useful in the presence of a hypermotile colon. They are contraindicated in those cases presenting a slow colon motor rate. In the latter the number of stools and the amount of pain are usually reduced by a properly adjusted daily dose of a saline cathartic and large fluid intake.

Adjustment of the diet to the needs of the patient is essential. A high protein low carbohydrate diet is better tolerated than the conventional high carbohydrate "colitis diets" traditionally in use. The importance of repeated investigation of the possibility of food allergy by the test diet method cannot be overemphasized.

The vitamin and mineral intake must be maintained at levels above the requirements of the normal individual. This necessitates supplementing the diet by the addition of special sources. Such supplements are essential during periods when the restricted test diets are in use. A constant watch must be kept for the early signs of deficiency disease and when evident they must be strenuously treated.

Autogenous vaccines, if recognized pathogens have been recovered on culture, appear to be helpful when used in conjunction with the other methods of treatment. Evaluation of the effects of vaccine therapy, however, is often difficult, particularly in view of the psychic effect on many patients who strongly believe in their efficacy. On theoretical grounds the rationale for the use of antisera seems less well grounded. I have not been impressed by the results of bacteriophage treatment in this disease.

Certain general measures are applicable. Definite foci of infection should be appropriately treated. Education of the patient to cope more successfully with his psychologic problems is frequently important. The effort to achieve formed stools, especially by the use of bismuth, is ill advised, since it adds to the already complex mechanism—the factor of mechanical trauma to the inflamed mucosa. I believe that the stools should be kept liquid or semiliquid until healing is complete.

What results are to be anticipated from medical management? It is unfortunate that the word "cure" has been used in connection with chronic ulcerative colitis. Too frequently it appears as a chronic progressive disease exhibiting periods of spontaneous activity and quiescence. Fifty-one of the patients have had recurrences or have shown continuous activity of the colitis with failure to respond satisfactorily to treatment. It is impossible to say that after any given period of freedom from activity the disease will not recur. In this respect it resembles the problem of pulmonary tuberculosis. It is impossible to be certain from the patient's symptoms or lack of symptoms that healing has actually occurred unless confirmation is obtained by both the sigmoidoscope and the x-rays.

\* Four cases treated surgically.

In this respect also the problem resembles that of tuberculosis. Consequently it seems most desirable to borrow from the terminology of the latter disease and to substitute the term "apparently arrested" for "cured."

Twenty-three of the cases are apparently arrested, forty-four are definitely improved but not healed, thirteen are unimproved and death occurred in five.

#### SURGERY

Prognosis in the individual case depends necessarily on the extent of irreparable damage to the colon and on identification and control of the factors operating to maintain activity of the disease. When extensive anatomic changes have occurred it is vain to hope for restoration to normal. Many such cases constitute serious problems of management. The complications resulting from chronic sepsis are common and, as was the case in two of my fatalities, these complications may lead not only to chronic invalidism but to death of the patient.

In the last few years there has been an increasing tendency to include radical surgery among the available therapeutic measures. The selection of cases and the decision as to when to resort to operative intervention imply the necessity for joint medical and surgical study and supervision both before and after operation. The detailed management of these problems should be carried out under the direct supervision of the senior physician and the senior surgeon of the group. In conjunction with Dr. Henry W. Cave such a detailed and combined approach has been made an

colon. It is also wise not to make the loop colostomy but to divide the bowel and its mesentery for some distance so as to try to obviate the jumping over of the infection. I need not say that the object is to put the diseased bowel completely at rest. There is considerable discussion regarding the value of irrigation of the distal loop. I believe it has a distinct value and cannot be duplicated by enemas without colostomy.

If the disease has begun to invade the transverse colon, of course, there is no alternative except to do an ileostomy or to depend entirely on medical management in the hope of arresting the spread of the process. The choice depends on the condition of the patient. If there is no improvement after adequate medical treatment, ileostomy is advisable early rather than late; for, if the disease process is arrested, the ileostomy may be changed to a colostomy after a long period, provided the process has not extended into the ascending colon.

If the entire colon is involved and the patient does not respond to medical management, ileostomy becomes imperative and the condition of the patient spells the optimal time. In the performance of ileostomy it is again necessary to divide the bowel at that point and institute through and through irrigation. The future course depends entirely on the convalescence of the patient. If he improves, gains weight, has no symptoms of toxic absorption and is not troubled much with frequent emissions from the rectum, I do not think it is necessary to subject him to colectomy. On the other hand, if he still seems toxic and does not gain weight, I think colectomy is indicated. If colectomy is done, it is best to use graded procedures, employing two or three operations as outlined by Rankin, Cattell and others.

In a review of 137 cases of chronic ulcerative colitis which were seen at the Cleveland Clinic in the past ten years, roentgen examinations showed that fully one half were limited to the rectum or left half of the colon. Many of these have eventually gone on to involve the entire colon in spite of all treatment. I would interpret that by picturing an invasion of upper segments of the bowel with each recurrent attack.

This brings me to the question Is it not possible for this section to outline what it would call adequate treatment? Then could not sufficient time be taken to try out these different treatments to determine which were most satisfactory or which failed, even though this might be a year or even two years? If we could know that certain therapy under certain circumstances would fail to give relief, why delay surgery? My plea is for surgical intervention while the lesion is limited to the left side. It should be remembered that, following surgical treatment, the patient should not be abandoned. Medical treatment is just as necessary at this time as at any other. If a specific should be introduced, the colostomy could be closed. If further surgery is necessary, it would involve removal of only the left half of the colon instead of the entire colon and the patient would, in the end, have a colostomy instead of an ileostomy.

The segmental variety, viz., that in which only a part of the colon may be attacked, the ascending, transverse or descending colon or any combination of these, constitutes about 5 per cent of the entire group. Here again surgical treatment should not be delayed too long for fear that the entire colon will become involved.

## PROGNOSIS OF ULCERATIVE COLITIS

J. H. WILLARD, M.D.

J. F. PESSEL, M.D.; J. W. HUNDLEY, M.D.

AND

H. L. BOCKUS, M.D.

PHILADELPHIA

Although the literature contains many references to the etiology, treatment and complications of so-called idiopathic ulcerative colitis, there has been little written concerning the natural history and the final outcome of cases of this disease. Such a study is essential before any definite evaluation of specific therapeutic measures can be made. In an effort to obtain information regarding the prognosis in this type of ulcerative colitis we have reviewed our records of the past twelve years and from 100 cases have selected sixty-six the records of which are complete. These have either terminated fatally while under observation or have been followed for a period of more than three years. The thirty-four cases which were not used lacked complete follow-up data. Twenty additional cases of various types of colitis were discarded because of atypical manifestations or incomplete diagnostic records. This group included amebic disease, tuberculous colitis, bacillary dysentery, regional colitis, ulcerative proctitis with positive Frei tests and other types of colitis which could not be classified definitely. This method of selection probably does not give an accurate cross section of the prognosis of the disease, since it is likely that many of those who failed to return for follow up are patients with the milder types of disease who have spontaneously improved, while those who have died under observation and those followed over a period of years probably were the more severely ill patients.

### DIAGNOSIS

All patients included in this series had a history of varying degrees of diarrhea, passage of blood, mucus or pus in the stools, abdominal cramps, febrile reactions and other signs of active disease. The diagnosis was established and the course followed in all cases by sigmoidoscopy and x-ray examinations. Only typical cases were accepted; such as those showing, by sigmoidoscopy, diffuse mucosal involvement with multiple military ulcerations, either active or healing, with pitting and an easily traumatized mucosa. Polypoid hyperplasia or actual polyposis was frequently seen. Cases presenting an atypical appearance of the rectal or sigmoidal mucosa were discarded. All cases were studied with the barium sulfate enema with one exception, an acute fulminating infection in which death occurred on the seventh day. While typical x-ray changes—narrowing, shortening and mucosal mottling—were not deemed necessary for the diagnosis, such changes were seen in most cases. Amebic colitis was ruled out by direct inspection of the intestine and numerous microscopic examinations of smears from the ulcerated areas and also repeated stool studies. Cultures were taken from all patients, many on numerous occasions, with special mediums to rule out *Bacillus dysenteriae* infection. Serum agglutination tests for *B. dysenteriae* were

From the Department of Gastro-Enterology, Graduate School of Medicine, University of Pennsylvania.

Owing to lack of space, this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the authors' reprints.

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1933.

done on all hospitalized patients. In the past five years many of the patients have had Frei tests; those with positive results have been eliminated from this series. No attempt to isolate the virus of venereal lymphogranuloma from intestinal discharges has been made.

FINAL CLASSIFICATION

The final status of each patient has been determined by the subjective complaints and objective examinations, including endoscopy and x-ray examination. Of the sixty-six patients fifty-two (79 per cent) were seen by one of us at the last visit. In nine instances (13.5 per cent) the final opinion was based on the report of the referring physician, while five patients (7.5 per cent) reported by letter. These final reports were compared with the original reports and the results tabulated as follows:

1. Death: Those dying (a) of the disease, (b) following operation or (c) from intercurrent causes.
2. Progression: Those showing continuance of or increase of symptoms with extension of x-ray involvement or occurrence of complications.
3. No change: Those showing continuance of symptoms with no significant change in the endoscopy or x-ray examination.
4. Slight improvement: Those with (a) less active symptoms or more prolonged remissions, (b) general clinical improvement with or without objective change or (c) objective improvement with little symptomatic change.
5. Definite improvement: Those having (a) few or intermittent symptoms, (b) definite healing but with remaining evidence of disease by sigmoidoscopy (pitting, polyposis, easy trauma) or (c) x-ray regression.
6. Remission: Those with (a) complete disappearance of active symptoms, (b) normal appearing mucosa

except for possibly slight pitting or residual non-inflamed polyps, (c) lack of x-ray evidence of activity although narrowing or shortening might remain. The remission was at least a year in duration before being so classified. We realize the inaccuracies of such a classification but believe it to be the best for our purpose.

TREATMENT

Since it has been our practice to use many therapeutic measures (table 1) concomitantly, no attempt has been made to draw definite conclusions regarding the value

of any single therapeutic procedure. The accompanying table indicates the frequency with which various measures were used. Particular efforts were made in every instance to keep the patient's morale at the highest possible level. This form of psychotherapy was considered most important.

Surgery was resorted to in fifteen cases (23 per cent) and included twelve ileostomies, two cecostomies and one colectomy.

DESCRIPTION OF CASES AND RESULTS

The cases have been grouped according to the course of the disease into the following types (table 3):

TABLE 3.—Analysis of Results

chronic relapsing, chronic continuous and acute fulminating. No further classification was attempted because of the extremely variable course of the individual case. The association of fever or toxic manifestations and the relative severity of subjective complaints, such as the number of stools, relative amounts of pus and blood and the presence of abdominal pain, seemed too variable for accurate analysis. The sigmoidoscopic picture also was so variable that no definite segregation of types seemed possible.

In a great majority of our cases the disease ran a chronic course. Thirty-three (50 per cent) were of the chronic relapsing type with irregular remissions and relapses, many presenting a seasonal relationship (spring and fall); in twenty-five (38 per cent) the disease had a chronic continuous course, and eight (12 per cent) were of the acute fulminating variety. This incidence of acute fulminating cases is higher than in other reported series and may be accounted for by the fact that most of our patients were seen in the gastrointestinal clinic of a general hospital associated with a teaching institution in a large city. It is likely that more acute cases find their way to such a clinic than to clinics farther removed from centers of population, such as the Mayo Clinic, Ruthin Castle, or the New Lodge Clinic attended by Hurst.<sup>1</sup> In our experience the acute fulminating type of disease results in death in a relatively short time (from one week to three months) or goes on to practically complete recovery. Five of our eight patients died and four were operated on. None of the patients who recovered had been

1. Hurst, A. F.: Prognosis in Ulcerative Colitis, *Lancet* 2:1194-1196 (Nov. 23) 1935; Ulcerative Colitis, *Guy's Hosp. Rep.* 85:317-355 (July) 1935.

subjected to operation. The best chance of complete remission is in the chronic relapsing type. This occurred in 39 per cent and definite improvement or remission occurred in about 70 per cent. No change was noted in about 15 per cent of this group, while about 15 per cent died. The chronic continuous type of disease resulted in death of one third with an additional 29 per cent having poor results. Only 37 per cent gave a satisfactory response and of those only 8 per cent had a sustained remission.

## SEX

The distribution between the sexes was almost equal, there being thirty-four females and thirty-two males. There were twenty-eight of Jewish extraction and three Italians. Five Negro patients were included, all females; the Frei test was negative in three of these but was not done in two earlier cases. As will be seen in table 3 and chart 1, there was no significant difference in the course of the disease in the two sexes except for a slightly higher mortality rate in females.

## AGE

The greatest number of cases appeared in the third and fourth decades, 65 per cent being between 20 and 39 years of age. With anamnesis to determine the age of onset of the disease—a somewhat inaccurate procedure, but of more value in a study of the natural history than the age at which the patient first came under observation—it appears that 82 per cent of the patients first had symptoms of the disease between the ages of 10 and 49. Only 7.5 per cent dated the onset at an age over 50 years (table 2). Although the group is too small for statistical analysis, it is of interest that

Chart 1.—Results in entire series, showing proportion of patients operated on.

the disease began in the teens more frequently in males than in females (10:6) but that in the years between 20 and 29 there was a much greater incidence in females (16:6). The males again lead in the next decade (10:6). Those favoring a psychogenic pathogenesis of ulcerative colitis might infer that the teens offer more psychic difficulties to the male sex, while the twenties offer the greater adjustment problems to the female. The age of onset seems to make little difference in the

prognosis, although the mortality rate was somewhat lower in those whose disease began between the ages of 10 and 19 years.

## DURATION OF SYMPTOMS

The duration of symptoms when seen by us varied from a few days to more than seventeen years. Twenty-four patients (36.3 per cent) gave histories of less than one year's duration, twelve (18 per cent) from one to

Chart 2.—Duration of symptoms, extent of involvement determined by x-ray examination and type of disease in entire series. None indicates no involvement; R & S, involvement of rectum and sigmoid; L. C., involvement of left colon; entire, involvement of practically the entire colon; Ac. Ful., acute fulminating course; Ch. Cont., chronic continuous course; Ch. Rel., chronic relapsing course.

two years, sixteen (24 per cent) from two to five years, nine (13.6 per cent) from five to ten years and five (7.5 per cent) ten years or more. It is of interest that these five patients are all living and at present have had the disease for more than twenty years, the longest time being twenty-seven years. The shortest total duration of the disease was two weeks in a patient who died of a peculiarly virulent fulminating attack.

The highest mortality and lowest rate of improvement were seen in those giving a history of symptoms of less than one year. Those with histories of over ten years' duration are all alive, but only one of the five has had a remission. Regardless of the duration, the incidence of remissions was between 20 and 33 per cent.

A possible explanation of the high mortality figures in this series is the inclusion of eight cases of the acute fulminating type which carried a mortality rate of 62.5 per cent. These five rapidly fatal cases represent 7.5 per cent of the total group. In Bergen's<sup>2</sup> recent figures only twenty-one of 871 cases, or 2.4 per cent of the total group, presented this fulminating type. It is difficult to obtain from other papers the incidence of these acute cases; hence comparisons are impossible.

## EXTENT OF X-RAY INVOLVEMENT

Classification as to extent of involvement of the colon as determined by barium sulfate enema examination also has been attempted. Narrowing, shortening, rigid-

2. Bergen, J. A.; Jackman, R. J., and Kerr, J. G.: Studies on the Life Histories of Patients with Chronic Ulcerative Colitis with Suggestions for Treatment, *Ann. Int. Med.* 12: 339 (Sept.) 1938.

ity or lack of haustrations, or extreme irritability and irregular mucosal outlines have been considered in this estimation. Since clearcut demarcation is rarely seen, no sharp distinction has been drawn. The cases were divided into four groups (table 3): (1) those presenting no definite x-ray changes, (2) those presenting

TABLE 5.—Final Results

	Cases	Per Cent of Total

involvement of the rectum and sigmoid only, (3) those presenting disease of the left colon (not beyond the midtransverse), and (4) those presenting extension to the right colon or complete colonic involvement. Sixty per cent of the patients showed x-ray changes in the rectum and sigmoid or extension to the left colon, while 21 per cent showed no definite x-ray signs and 17 per cent showed disease of practically the entire colon.

thirty-one (47 per cent) are either dead or not improved, while thirty-five (53 per cent) are improved or in remission (table 5).

The literature<sup>3</sup> contains reports of mortality rates ranging from 9.3 to 40 per cent. It is difficult to compare these figures because of different sources of material and various criteria for classification. The incidence of fulminating disease is apparently higher in our series than in others reported. This undoubtedly has an important influence on our statistics regarding mortality and improvement. An additional factor influencing the final figures is the inclusion of deaths from all causes. Five patients died of diseases not directly related to the ulcerative colitis. These include three cardiovascular deaths, two of which occurred during a remission of the colitis; one suicide of a patient who was somewhat improved after cecostomy, and one death from meningitis secondary to mastoiditis of a patient whose colitis was somewhat improved.

SURGERY

Another factor influencing the results is the frequency with which surgery was attempted during a part of the period covered by this survey (tables 7 and 8). The postoperative mortality, in our experience, has been 42 per cent. Operations were performed

TABLE 8.—Surgical Cases

W. F.....	♂	43	13 mo.	L.C.	Polyposis, bleeding	Fair	Ileostomy	Fair		4 yrs.

L.C. = left portion of colon.

R&S = rectum and sigmoid.

P.O. = postoperative.

The group showing only involvement of the rectum and sigmoid presented the best outlook; the poorest results were obtained in those with extension to the left colon. Of those with no demonstrable x-ray changes a large proportion had an acute fulminating course, accounting for the high mortality in this group.

SUMMARY OF RESULTS

Forty-seven (71 per cent) of the total group of sixty-six patients are alive and nineteen (29 per cent) are dead. Twelve (25 per cent) of the living patients have shown progression or no improvement in the disease; seven (15 per cent) are slightly improved and twenty-eight (60 per cent) are greatly improved or in complete remission. If the entire group is considered,

in 22.7 per cent of the entire series (58 per cent of the fatal cases). Only 27 per cent of the patients who were operated on have lived (four patients). Two of these are decidedly uncomfortable with their ileostomies, one has improved following ileostomy and one has shown slight general improvement after a colectomy done six months ago.

A further study of the fifteen cases referred for surgery shows that in four instances operation was

Bargen, J.

attempted as a last resort in extremely ill patients after all other measures had failed to halt the progress of the disease. Four additional patients were poor risks because of toxemia or loss of blood or both; one of this group is living. Six patients were in fair condition at the time of operation but surgical intervention was decided on because of the progressive course of the disease or because of the presence of polyposis, excessive bleeding or complications such as arthritis and perirectal abscess. Three of these patients are living, two

vention. During the past three years only the most extremely ill patients have been operated on. Many who formerly would have been referred for surgery because of the severity of the disease are now being continued on medical treatment. It is our impression that the more conservative plan is decreasing the mortality rate, although sufficient time has not yet elapsed to evaluate results.

#### CAUSES OF DEATH IN NONSURGICAL CASES

There were eight deaths in nonsurgical cases, an incidence of 12 per cent, or 42 per cent of the deaths in the entire series (table 9). The causes were classified as cardiovascular disease three cases, inanition two cases, acute toxemia one case, toxemia of pregnancy with nephritis one case and meningitis one case. Two of these patients did not die directly as a result of the ulcerative colitis. One died of meningitis secondary to mastoiditis. The other died of cardiovascular disease one year after a remission of the colitis. A third patient was practically symptom free for several months until pregnancy and renal damage appeared.

Three patients had the acute fulminating type of disease, two had the chronic relapsing and three had the chronic continuous type. Four of the eight patients were under 30 years of age. Of the four over 30, three were past 50. Three of the four past 30 died of cardiovascular disease; the fourth had an acute fulminating infection the total duration of which was only two weeks; autopsy showed extensive involvement of the entire colon. Seven of the eight deaths in this group occurred in females.

With two exceptions the fatal nonsurgical cases belonged in the short duration group, six of the patients having had the disease less than one year. The two exceptions were the patient who died of meningitis secondary to mastoiditis, having had ulcerative colitis for three years, and a woman aged 65, who died of cardiovascular disease after a remission of the colonic symptoms, which had begun twelve years before.

with ileostomies and one with a colectomy; one who had a cecostomy improved somewhat but committed suicide a few months later. The remaining patient was in good condition at the time of operation, but because of persistent symptoms for five months following a five and one-half year intermittent history, surgery was attempted. She died after operation of volvulus and peritonitis.

The causes of postoperative deaths included peritonitis (three cases), obstruction and peritonitis (two cases) and continued toxemia (three cases). Other causes of death in patients who were operated on were liver abscess (one case), iliac phlebitis (one case) and suicide (one case).

Operation (ileostomy) on two patients with the acute fulminating type of disease ended fatally in both. Ileostomy was done in five chronic relapsing cases with four postoperative deaths. Eight operations were done in the chronic continuous group: five ileostomies, two cecostomies and one colectomy. Two patients died following operation, three have died since and three are living.

There seemed to be little relationship between the results of operation and the duration of symptoms, although the highest immediate death rate appeared in those with symptoms from two to five years in duration. The extent of involvement of the intestine as judged by x-ray examination also had little bearing on the results, although the mortality was slightly higher in those with entire colonic involvement.

In view of this experience with surgery we have become more conservative in advising operative inter-

The x-ray changes in the fatal nonsurgical group varied from no change to involvement of the left colon. None showed disease of the entire colon.

#### COMPLICATIONS

The most frequent complication in this series was polyposis or polypoid hyperplasia of the colonic mucosa as seen endoscopically. Twenty-six patients showed this change at some time in the course of the disease. In general, this complication was not associated with any marked change in the outcome, although the rapid development of polypoid hyperplasia in the acute fulminating type of disease was usually accompanied by profuse and persistent bleeding. Some of these attacks ran a rapidly fatal course.

Other complications in the order of their frequency (table 10) were rectal stricture, allergy, arthritis, peri-

rectal abscess, fistula in ano, perforation of colon and abscess of liver. The incidence of syndromes of definite vitamin deficiency was low. No cases of carcinoma were encountered. Allergy was noted in association with five cases, in three of which this condition may have been of some etiologic importance.

## COMMENT

It is to be emphasized that in selecting these sixty-six patients for study extreme care has been used to exclude all cases which did not exhibit the typical picture of so-called idiopathic ulcerative colitis in one of its various stages. The primary requisite was diffuse involvement of the mucosa of the rectum and sigmoid. Cases presenting isolated ulcerations or patchy involvement were not accepted. We have not included cases of right-sided colitis, regional colitis, ileocolitis or regional ileitis or proved venereal lymphogranuloma. It is our impression that much of the literature concerning ulcerative colitis deals with cases in the latter classifications and not entirely with the type of disease we have chosen to discuss. If cases of regional colitis or right-sided colitis and ileocolitis had been included, our operative statistics would have been much more favorable, since in our experience most of these patients do well with surgical treatment.

The estimation of final results in this series was based on actual examination of the rectal mucosa in 80 per cent of the cases, and only those patients who had been symptom free for one year and who showed no sigmoidoscopic evidence of activity were reported as being in remission.

We believe that the type of colitis discussed in this paper is a clinical entity and that it corresponds to the disease described by Bagen as "thrombo-ulcerative colitis." However, the bacteriologic studies on these cases failed to indicate a specific etiology for the disease.

The serious nature of ulcerative colitis is indicated by the mortality and morbidity figures both in the literature and in this series. In general, the methods of treatment seem to have little effect on the statistics, although the use of multiple procedures makes definite conclusions impossible. It has been our experience that no single therapeutic measure has produced striking results in more than an occasional patient. Some patients have responded well to one procedure during one relapse and to another procedure during a subsequent relapse. The entire armamentarium frequently fails to produce favorable results.

Surgical intervention, in our experience, is one of the factors resulting in a higher mortality rate. This is in agreement with the experience at the Mayo Clinic, where over a period of eleven years (1923-1934) the postoperative mortality was slightly over 52 per cent. This cannot be considered a criticism of the surgical technic but indicates a greater need for conservatism in advising surgical treatment in a disease which entails such a high operative risk. We have been agreeably surprised in the past few years to find in several instances in which ileostomy seemed imminently necessary that a sudden improvement occurred without operation. Many of these patients would have been operated on a few years ago. The nonoperative mortality rate has not been appreciably altered by this more conservative plan.

The acuteness of the infection and the resistance of the patient are obviously important factors prognostically. In this series the highest mortality rate appeared

in those patients with short histories, a finding which is at variance with the figures of Crohn and Rosenak<sup>3</sup> and others. This is probably due to the inclusion of a larger number of cases of acute fulminating disease. Patients with mild symptoms of short duration clearly offer the best prognosis, but many of these seen prior to three years ago were not included in our series because of lack of follow-up data. The greatest number of deaths occurred in those having had the disease for six months or less. In most of the fatal cases the disease had an acute febrile, toxic or fulminating course. The patients whose disease had lasted from seven months to a year showed a lower rate of mortality and a greater incidence of improvement or remission. We have been unable to determine any definite factors contributing to the rapidly fatal course of the disease in some instances.

An increase in the mortality rate was noted in those patients having had symptoms for from two to five years. This might be explained by the debilitating effect of the chronic disease and also by the relative number of operations performed in this group in an effort to relieve long-standing symptoms. After five years the mortality figures are fairly low, suggesting the gradual development of a higher degree of resistance. It is of interest that the percentage of improved or cured (?) patients in this group is the highest of any in the series (77 per cent). Patients having had the disease for more than ten years apparently seldom die as a result of it even though followed for many years. Improvement is often seen in these patients with long-standing disease, but remissions are uncommon.

The x-ray appearance of the colon is not a reliable prognostic guide. If the disease is mild and the involvement is superficial, no appreciable x-ray abnormalities are to be expected. In the very acute fulminating cases, pathologic changes in the intestinal wall may not be sufficiently invasive to produce a so-called characteristic x-ray appearance. A "fuzzy" silhouette or diffuse mottling of the intestine after injection of air may be present. The patients with involvement of the rectum and sigmoid as shown by x-ray examination had a higher morbidity but a lower mortality than those with negative x-ray examinations. X-ray evidence of disease of the left colon was associated with the greatest mortality and the lowest rate of improvement. In the patients showing involvement of the entire colon the rate of mortality was not greater than in those with minimal involvement, and improvement or remissions occurred about as frequently as in the patients with negative x-ray evidence. It would appear that acute toxic exacerbations are less prone to develop in patients with definite narrowing of the entire colon. The disease has "burned itself out," leaving a thickened fibrotic tube with very little chance for absorption or further destruction of tissue.

Finally it should be emphasized that the prognosis in any case of ulcerative colitis must be guarded. Some of the most severely ill patients, with extensive involvement, severe and continuous bleeding and symptoms and signs of marked toxemia, may suddenly or gradually show improvement and finally go into a complete remission. In most cases of this type we have been unable to attribute this change to any one specific therapeutic measure. We should like to stress the importance of continuous active treatment, utilizing every measure to maintain nutrition and resistance at the highest possible level.

## CONCLUSIONS

1. So-called idiopathic ulcerative colitis is a serious disease, being associated with a mortality of from 10 to 40 per cent in various reported series.

2. The results in any given series probably depend more on the types of disease included, the time followed and the incidence of surgical procedures than on specific therapeutic measures used.

3. In our experience, no single therapeutic measure is particularly effective in any number of patients. A regimen including a great variety of procedures would seem to offer the best chance of success in any given case.

4. An immediate postoperative mortality of 42 per cent and a death rate of 73 per cent in surgical cases are strong arguments in favor of a conservative attitude toward surgical intervention in this disease.

5. Sex was apparently not an influential factor in the final results.

6. The age of the patient at the onset of the disease seemed to make little difference in the results obtained in this series. Contrary to the general impression, the appearance of the disease after the age of 40 did not improve the outlook materially.

7. The highest mortality rate was found in the acute fulminating type of disease. With the exception of those having had symptoms for from two to five years, there seemed to be a gradual lowering of the mortality rate inversely proportional to the duration of the disease. However, marked improvement was seen less frequently in the very long-standing cases.

8. Better results were obtained in the chronic relapsing than in the chronic continuous type of disease.

9. The extent of x-ray involvement was not a reliable prognostic sign.

2022 Locust Street.

## ABSTRACT OF DISCUSSION

ON PAPERS OF DR. MACKIE, DR. JONES AND DRs. WILLARD, PESSER, HUNDLEY AND BOCKUS

DR. WILLIAM FITCH CHENEY, San Francisco: The incidence of the disease must be greater in Eastern cities than in San Francisco, because the number of cases the authors report are larger than I have seen, and yet my experience has coincided closely with that which they have expressed. I agreed with Dr. Mackie's statement that there is no reliable bacteriologic finding either in cultures, stool cultures or in agglutination tests. The appearances by the proctoscope are similar in one locality as in another, and the x-ray appearance of the colon in any protracted case is the same as demonstrated today. The important point is treatment, and this so far has been of little avail. The various serums, such as the polyvalent, antibacillary serum which Hirsh in London so esteems and Crohn in New York reports favorably on and the ulcerative colitis antistreptococcus serum of Bergen, have failed to give satisfactory results. All the different plans recommended as regards diet, medication and rectal injections we have used, but remissions and exacerbations occur in spite of all. There are certain cases in which surgical operation is inevitable, and perhaps we have waited too long in some cases, but the fault is largely with the patient. They don't like it and they postpone it as long as possible. Dr. Mackie reported one case in which he had remarkable results with concentrated liver extract. We have been using in these cases recently a concentrated liver extract. We have given it intramuscularly three times a week at the outset or more often, if the case is a serious one, twice a week for the next month, and after that in dosage sufficient to control, sometimes once a week, sometimes once in two weeks. There have been eight cases treated in this way during the past year, with what I consider remarkable results. The credit for this work belongs to Dr. Garnett

Cheney, but I speak as an observer and not from hearsay. We have seen improvement in weight, comfort and efficiency, and in bowel condition as shown by the proctoscope; and if we discontinued it we saw a relapse, to be succeeded by improvement when we resumed it, but I agree again with Dr. Mackie that treatment must be continued. He compares the disease to tuberculosis. I would compare it to pernicious anemia in this respect. I realize that the time during which this has been tried is short and the number of cases, eight in all, is few; but at least, after years of experience in these cases, I have never seen anything act as well as this has.

DR. JOHN H. FITZGIBBON, Portland, Ore.: In treating ulcerative colitis, our point of view must be extremely broad. As in the care of peptic ulcer, treatment must be planned over a prolonged period, divided into two parts: the immediate treatment with an attempt to heal the condition, followed by lifelong observation and care to prevent recurrence. The patient must be treated as an individual and there is no way of standardizing methods. Each patient has his idiosyncrasies and responses to treatment. The patient is entitled to know the truth about his condition, but when the truth is presented to him or to his parents, if he is a youngster, it should be presented in an optimistic way. One of the chief difficulties in obtaining good results has been the hopeless attitude on the part of many of the medical profession. Patients or their families frequently come with a hopeless feeling about the disease and they are in a more or less desperate state of mind. This has led to delayed surgery, as Dr. Jones has emphasized. While I agree with Dr. Jones that the high mortality is chiefly because of late operation in the cases which come to operation, I am inclined to favor Dr. Mackie's outline of indications for surgery, which are conservative. Early surgical intervention, in my experience, has been rather unfortunate in several cases. When I have become alarmed and rushed the patient to operation, the mortality rate has been extremely high. On the other hand, when I have watched the patient and done everything possible to maintain his nutrition, vitamin intake and particularly his fluids, the results of operation have been better. Physicians should not feel hopeless about the prognosis. There is nothing more gratifying to a physician than to cooperate with a careful, conservative surgeon and obtain a good result in one of these cases. When we see an individual whose life is absolutely worthless, who spends practically all his time on the bedpan or in the toilet, who has no future whatever, and are able to aid him to become a useful citizen, our efforts are well worth while. The weight of such patient, a youth of 18 with long-standing colitis, 6 feet tall and weighing 80 pounds, after an ileostomy increased to 165 pounds. After complete resection of the colon he found employment and is helping to support his family.

DR. WILLIAM C. BOECK, Los Angeles: The view held before 1925 was that this disease should be treated primarily by surgery. Then in 1925, after the work of Bergen, we were led to believe that this disease could be treated by medicine. In the last thirteen years, as a result of the investigations of Bergen and others, I have come to four definite conclusions: 1. There is now an accepted clinical, roentgenologic and pathologic description of this disease which heretofore was quite unknown and was confused with tuberculosis and other conditions. 2. We are still in the dark as to the etiology. 3. This disease is known to be of a chronic relapsing type and it may go on for many years even though nothing is done for the patient. 4. There is a hopeless prognosis in many of the fulminating cases. It is generally agreed that the treatment is primarily medical to begin with. Furthermore, medical treatment is nonspecific and unsatisfactory. Probably medical cures are not brought about, but only an arresting of the disease. It may recur at any time. This was emphasized by Dr. Mackie. The surgeon, however, does bring about a cure when he performs a total colectomy, and that is the only "cure" I know of. Because of the unsatisfactory medical treatment there is again a trend toward surgery, and we have heard a plea today for colostomy, especially for those conditions which are limited to the rectum or the sigmoid-rectum portion of the colon. The only criticism that I would have for this procedure is

that in many cases the condition will remain limited to this area of the colon for years and never go any higher and such people cannot be induced to have a colostomy. Furthermore, I have had cases in which transverse colostomy has been done and the infection did not remain limited to the rectum but not only progressed to the ascending colon but also involved the stoma and even the skin of these patients. There isn't any assurance that just because one is going to do transverse colostomy one will limit it to the left side of the colon. It can go beyond that and has done so. A surgeon deserves a great deal of credit if he wants to operate on these patients. There is no other field of elective surgery with such a great mortality, even in neurosurgery. I think we should get together and spend some money on investigation to see whether we can't combine the medical and surgical treatment and obtain a better solution than exists at present.

DR. ARTHUR L. BLOOMFIELD, San Francisco: Surveying the whole field, none of us seem to be very happy about ulcerative colitis. You remember the despairing cry of the physician in Macbeth: "This disease passeth our art." I am afraid that is the situation with ulcerative colitis. We are mostly sail and very little anchor. It does seem to me of interest to line up ulcerative colitis with certain other "itises" which seem in many ways to be somewhat analogous. There is this very interesting group of chronic, semi-inflammatory, semidegenerative diseases the etiology of which is not clear. I might mention iritis, choroiditis, arthritis, hepatitis, along with ulcerative colitis. They all occur in very acute form and the patient may promptly get well and remain well, or they may begin in acute form and go ahead with a fulminating course, or there may be slower forms with relapses, finally passing into a chronic state. In all these diseases the etiology is unclear and, in all, attempts have been made to incriminate bacteria of one sort or another, usually with little success. It has been brought out that no specific etiologic agent has been proved. The most useful advance in recent years is the delivery of the patient with ulcerative colitis from the tortures which he used to have at the hands of physicians; namely, the defective diets which produced deficiency disease and the local, corrosive irrigations of the colon, which most physicians have pretty much abandoned. I should like to say one word to reinforce what Dr. Cheney said about concentrated liver extract. I am extremely cautious about therapy and still I have been immensely impressed by this series of cases. One of these patients is a young man who has been through the whole gamut of treatment, including sulfanilamide, with which, incidentally, I have had very poor results, fever therapy, vaccines, serums and high vitamin diets. At Dr. Cheney's suggestion I treated him with concentrated liver extract, and the result was remarkable. Of course, it is too soon to say whether he will be cured.

DR. JULIAN M. RUFFIN, Durham, N. C.: There are certain aspects of Dr. Mackie's paper which I wish to discuss. In my experience there has been no one organism which is constantly present. In a group of fifty patients the most frequent organisms were hemolytic *Endamoeba coli* and streptococci. Bagen's bacillus is inconstantly present, and I have been unable to grow a dysentery bacillus in a single case. Agglutinations were likewise negative. I feel, therefore, that there is no one organism which is responsible for the disease. Dr. Mackie has properly emphasized the importance of food sensitivity and certainly in some cases this does occur. I recall two cases in which a fulminating relapse immediately followed the ingestion of raw peanuts. The relationship of ulcerative colitis to a deficiency state is unquestionably true but I do not believe that ulcerative colitis can be regarded as a primary deficiency in the same sense as pellagra. A comparison of the proctoscopic appearance of the patients with ulcerative colitis with that of pellagra is of interest. In patients with pellagra who have the dermatitis but no sore tongue and no diarrhea the rectal mucosa is entirely normal. If, however, the patient has a sore tongue and diarrhea, invariably the rectal mucosa will be found to be diffusely inflamed and hyperemic, but never have I observed ulcers or the granular appearance which is so characteristic of ulcerative colitis. The importance of liver therapy has been pointed

out and in my experience marked improvement has been observed in certain cases following the use of liver extract. Dr. Mackie has given a most intelligent and comprehensive outline for the handling of the medical aspects of chronic ulcerative colitis.

DR. S. L. BERNSTEIN, Cleveland: I have no specific remedy for this disease but I want to make a slight contribution by telling of a result which I have had recently in a number of cases. I am impressed with what Dr. Cheney said about the use of liver, and in conjunction with that I have used enteric coated tablets of potassium permanganate 1 grain (0.065 Gm.) each.

DR. SIDNEY A. PORTIS, Chicago: I am sure that physicians are agreed that there is no specific etiologic factor at the present time producing ulcerative colitis. If there is no specific organism, it would seem logical that we should concern ourselves with those changes in the colon which predispose to secondary ulceration. What lowers the resistance of the colon that it should be the site of these lesions? Certainly bacillary dysentery may play a role. Bagen's organism may be found in a certain percentage of the cases. An interesting feature of this disease is that it practically always begins in the rectum and the sigmoid. Anatomically this is a fixed portion of the bowel. Therefore the trauma of hard, inspissated stools may irritate a sensitive colon and predispose to secondary ulceration. As Dr. Mackie has pointed out, this is one disease in which bismuth should not be used, because bismuth only helps to increase the consistency of the stool and make it more firm and in turn produces a pressure necrosis which promotes secondary ulceration. I have seen two cases at necropsy in which pressure ulceration from the use of bismuth has resulted. Further, I should like to call attention to the fact that the disturbances in metabolism and particularly mineral metabolism, with deficiency of chloride, may lower the resistance of the bowel wall and produce secondary ulceration. May not some of these cases, more or less, mirror the picture of an azotemia, and similarly may not an ulcerative colitis, associated with a uremic picture, reemphasize the fact that disturbances of nitrogen metabolism may be an additional factor? Just because a patient has an organic disease of the colon, associated with diarrhea, the psychogenic factors that may play a role in keeping up the gastrointestinal manifestations are frequently overlooked. Within the last year I have seen two cases of ulcerative colitis which did not improve under ordinary medical management, and with a psychoanalytic approach to their problem the diarrhea was almost completely ameliorated and there was a marked improvement in the clinical picture.

DR. JOSEPH FELSEN, Brooklyn: Based on experience in the East, chronic ulcerative colitis is nothing more than a late manifestation of bacillary dysentery. As the incidence of acute bacillary dysentery in this country, particularly during the past five years, is studied, one finds that the disease, according to actual figures available at the moment, has increased sixteen times. It appears to me, moreover, that the incidence of chronic ulcerative colitis has paralleled the increasing incidence of acute bacillary dysentery. Conclusive proof of this statement cannot be presented, however, until adequate follow-up studies of cases of acute bacillary dysentery are carried out, as were done in the Jersey City epidemic of 1934. Let me revert to some of the statements that have been made here this morning. I think it is very difficult to explain away twenty-one cases of chronic ulcerative colitis in which bacillary dysentery was definitely proved to be the etiologic agent. One cannot explain that away by any method of reasoning; moreover, in the other cases, let's say 80 per cent of them, the failure to obtain a positive culture does not necessarily mean that the original acute disease was not bacillary dysentery. In the acute form of the disease, the organism often disappears by the end of the tenth day. The serologic titer is no diagnostic criterion by itself. It is necessary to correlate all the various factors, epidemiologic, pathologic, serologic, clinical. As a result of such studies I feel more strongly than ever that chronic ulcerative colitis is nothing more than a late manifestation of bacillary dysentery. With regard to the surgical treatment, my experience coincides largely with that of many of the preceding speakers. The difficulties in surgery are chiefly these: Too much is expected of the

surgeon. If the surgeon will realize that the spread of intramural infection in the bowel from a segmental area of chronic ulcerative colitis is far beyond the reach of the naked eye and that no clue is afforded as to the extent of infection by the presence of mesenteric or mesocolic lymph nodes, he can readily understand why recurrences take place or why the patient dies of peritonitis. In New York, the cases I have been able to investigate have shown that the surgeon has cut through infected bowel or has overlooked a "skip" area, and the patient is no better after surgery than before. One cannot tell even in a postmortem specimen where the infection begins or ends.

Dr. A. H. AARON, Buffalo: The great majority of physicians have agreed that they do not know the cause of chronic nonspecific ulcerative colitis and that there are so many factors entering into the question that it is difficult without the most elaborate equipment to determine the etiologic factor in a very small group of those having the disease. One is left to try bacillary serum, then Barger's serum and vaccine, then all those agents that are going to be in the food factor group, and then the substances to solidify the stool. There is no intestinal antiseptic of any value; it has been agreed that the therapeutic enema has little value in the treatment of this condition. Rest is one of the most important factors. A diet can be arranged that will supply those factors which we honestly know something about, not a widespread vitamin administration of proprietary substances of whose exact action we know so little at the present time in this disease. I feel certain that when we hear of the excellent results of administration of liver in these cases we know we are dealing with the results of dietetic deficiencies due to prolonged ulcerative colitis. Please don't surfeit these patients with all these injections and therapy that we have been guilty of using. Remember that there is no factor in the cure of disease that equals rest and that we can establish a diet that will prevent them from acquiring deficiency states.

Dr. THOMAS T. MACKIE, New York: Emphasis has been placed on the therapeutic value of liver extract. I agree with Dr. Aaron that response to this preparation is indicative of failure to absorb or to utilize specific dietary factors which should be obtained from food. I have restricted liver therapy largely to patients presenting what I consider objective indications of deficiency disease. These comprise changes of the buccal and lingual mucosa similar to those seen in sprue, pellagra or pernicious anemia, and the gradual change from a microcytic to a macrocytic type of anemia. The caution that partial resection may be followed later by involvement of the remaining previously normal segment calls for reemphasis of the vital importance of complete study prior to resort to surgery. Such study may require months of observation to permit certain identification of contributory factors. These should constitute not only the basis of preoperative preparation but the basis of a permanent regimen for the patient after surgical intervention. For example, if successive addition and withdrawal of a particular food is accompanied by predictable exacerbation or quiescence of the inflammatory process, this food should be permanently forbidden. It is impossible to determine how far the colon may be sensitized or to predict the end result of continued exposure to the sensitizing agent. A recent experience with a case of the segmental type is illustrative. The entire colon proximal to mid-descending was extensively involved, the distal portion was normal. Preoperative dietary studies yielded clearcut evidence of sensitization to several foods, including milk and wheat. Following subtotal resection and ileosigmoidoscopy the allergic response was materially changed in character but not eliminated. Marked intestinal symptoms invariably follow the ingestion of foods previously found to disagree. A note of discouragement creeps into most discussions of the therapy of ulcerative colitis. Certainly this is justified with respect to achievement of complete cure by medical measures alone in many cases. On the other hand, many patients can be returned to a life of reasonable activity and of reasonable usefulness to the community and to themselves, granted adequate individualized study and cooperation. For the severe cases radical surgery must be considered. It is these cases particularly which require the most careful study prior to operation if operative mortality and follow-up results are to be satisfactory. The importance of the medical-surgical

team approach in both the preoperative and postoperative periods cannot be too strongly emphasized.

Dr. THOMAS E. JONES, Cleveland: With regard to Dr. Boeck's remarks about the jumping over of the infection, I tried to make it clear that if the colostomy is made properly it can obviate its occurrence. I have never seen a single case in which it has taken place. Maybe the organisms in Los Angeles are pretty high jumpers. Of course every surgeon will admit that the mortality is high. Why? Because patients have been carried on indefinitely under medical treatment and the only time the surgeon gets them is when they are practically moribund. We are not proud of that. We should like to obviate it but that is the reason for it—nothing else. It is just delay. Dr. Fitzgibbon has had an unsatisfactory experience with colostomy. Perhaps he has. I don't want him to have the misunderstanding that I jump right in and do it when the patient comes in. He is given a long period of rest and the operation is done in the quiescent stage, of course, and not as an emergency operation. I feel that Dr. Aaron has summarized this problem in a very sane manner. Put the patient to bed. Take two years, if necessary. Try allergy, vaccine, serum, diet, drugs, and if the patient has a recurrence, do a properly placed colostomy early rather than late.

Dr. J. F. PESSER, Trenton, N. J.: I should like to stress again the importance of continuous active treatment, utilizing every measure to maintain nutrition, and to improve the resistance to the highest possible level.

## THE INCIDENCE OF PRIMARY BRONCHIOGENIC CARCINOMA

PHILIP B. MATZ, M.D.

Chief, Research Subdivision, Veterans Administration  
WASHINGTON, D. C.

A review of the literature indicates that the incidence of primary bronchiogenic carcinoma has shown a definite increase in recent years. The increase has been shown to have occurred not only in the United States and Canada but in the various European countries as well, particularly Germany. Pässler in 1896 collected fifty-seven cases of cancer of the lung, as compared with Adler, who in a study made in 1912 was able to collect 360 cases from the literature. In his study Adler stated that failure to recognize this type of tumor had for a long time sustained the belief that it is a rare condition.

### INCIDENCE

Klotz<sup>1</sup> cited the literature showing the varying incidence of primary bronchiogenic carcinoma found by observers in succeeding periods. Thus Rheinhardt in 1878 noted cancer of the lung in 0.057 per cent of all autopsies; Fuchs in 1885 observed it in 0.065 per cent, Wolf in 1894 in 0.223 per cent, Oerstrom in 1907 in 0.31 per cent and Briese in 1916 in 0.46 per cent, and Barron in 1922 observed primary bronchiogenic carcinoma in 0.9 per cent of autopsies.

In recent years the incidence has risen at an accelerating rate. The continued rise, however, has not been noted equally in all localities, and there are reports from isolated clinics and hospitals where the incidence of primary cancer of the lung remains low. In 1934 Hill<sup>2</sup>

From the Medical and Hospital Service, Veterans Administration. Technical assistance in this study was rendered by E. K. Steet, A. Bamberg and Blanche B. Wilcox.  
Dr. Matz died June 25, 1938. At the time of his death he was chief of the Research Subdivision, Veterans Administration.  
Read before the Section on Pathology and Physiology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.  
1. Klotz, Oskar: Cancer of the Lung: with a Report upon Twenty-Four Cases, *Canad. M. A. J.* 17: 989-996 (Sept.) 1927.  
2. Hill, R. M.: Primary Cancer of the Lung: Its Incidence and Pathology, *Edinburgh M. J.* 41: 320-333 (May) 1934.

stated that cancers of the lung are seen in about 1 per cent of all autopsies and comprise more than 8 per cent of all malignant neoplasms discovered post mortem. In England the statistical data show a steady rise in the incidence of primary bronchiogenic carcinoma. Studies by German observers indicate that pulmonary neoplasms of this type have shown an increased incidence during the past few years, both those discovered ante mortem and those seen post mortem. The statistical data of other European countries also indicate an increasing incidence of this form of neoplasm. Simons<sup>3</sup> summarized the statistical proof of the increasing incidence of the disease in North America by tabulating the figures presented by eleven authors. The material included 22,754 necropsies and 669 carcinomas, of which 137 were pulmonary cancers. Cancers of the lung observed at autopsy increased from none in 1899 to 1.55 per cent in 1930. A similar increase in the ratio of cancers of the lung to all cancers was found; the percentage varied from 5.88 during the years 1910 to 1914 to 8.28 during the years 1925 to 1928.

#### INCIDENCE OF PRIMARY BRONCHIOGENIC CARCINOMA IN THE VETERANS' GROUP

The present study was initiated in order to ascertain whether or not additional knowledge could be derived from the statistical data of the Veterans Administration on the incidence of carcinoma in general and of bronchiogenic carcinoma in particular. It was thought that it might be possible to learn the effect of advancing age on the incidence of primary bronchiogenic carcinoma in a selected group of men of whom the largest number had reached the cancer age period.

The data in this study are based on autopsies performed in the hospitals of the Veterans Administration. Permission for autopsy is obtained in about 41 per cent of deaths of veterans in Veterans Administration hospitals; the percentage varies with the type of hospital, being highest in those primarily for patients suffering from medical and surgical disorders.

A study of table 1, showing the data from 1927 to the first six months of 1937 inclusive on the percentage relation of primary bronchiogenic carcinomas to all autopsies, indicates that the percentage varied from a low of 0.4 to a high of 5.3. It also varied from year to year; the highest percentage was found in the six month period of 1937. The figures for 1927 to 1937 indicate that the percentage relation of primary bronchiogenic carcinomas to all carcinomas varied from a low of 2.7 per cent to a high of 23.4 per cent. In 1928 no bronchiogenic carcinomas were observed at autopsy. The consolidated figures show that 13.7 per cent of all carcinomas were of the primary bronchiogenic type.

The total number of primary bronchiogenic carcinomas from 1927 to the first six months of 1937 inclusive was 160. All carcinomas found during this period numbered 1,167, and the autopsies performed, 7,398. In studying the figures it was found that there had been a steady rise in the number of all carcinomas, as well as in the bronchiogenic type, from 1931 to 1937.

#### NATURE OF INCREASED INCIDENCE

The literature on the nature and the causes of the increasing incidence of primary bronchiogenic carcinoma is extensive. Most of the studies have been made by European observers. However, a number of American clinicians and pathologists also have investigated

the various phases of this problem for the purpose of learning whether the increased incidence of this type of tumor is absolute or relative.

The observations of Rosahn<sup>4</sup> at the Boston City Hospital are most convincing as to the nature of the increased incidence. In the period 1925 to 1928 the percentage relation of all cancers to all autopsies at the Boston City Hospital increased by 20 per cent, while the percentage relation of primary carcinoma of the lung to total autopsies increased by 81 per cent and the percentage relation of primary carcinoma of the lung to all cancers showed an increase of 49 per cent. These figures indicate that the increase of the incidence of primary bronchiogenic carcinoma was much greater than the increase of the incidence of all cancers. The data are suggestive of an absolute increase of primary cancer of the lung. At the Mayo Clinic, Lemon, Vinson, Moersch and Kirklin<sup>5</sup> found a steadily increasing number of primary bronchiogenic carcinomas since 1925. There were almost three times as many positive diagnoses made of this form of cancer in 1931 as in 1927. These observers reached the conclusion that there has been an actual increase of this type of tumor.

Simons<sup>3</sup> expressed the opinion that the incidence of the disease has increased both absolutely and relatively; that continued suggestions that such an increase is only apparent are refuted by the facts; that the increase was gradual until the early 1900's, the gradient of increase having become constantly steeper since then, and, finally, that in many localities the greatest incidence seems to have been reached in 1924, while in others the frequency is still advancing.

In the foreign literature also the question whether the increased incidence of primary bronchiogenic carcinoma is absolute or relative shows a divergence of opinion. In Great Britain, Simpson,<sup>6</sup> after a study of his data and the data of others, concluded that the increased incidence of carcinoma of the lung is a real one and that it is not associated with a comparable increase of total carcinomas.

Hanf made a study of the incidence of primary bronchiogenic cancer in the Pathologic Institute of the University of Berlin. She noted that the increase was parallel with that of other cancers. Her conclusion was that the increase of primary bronchiogenic carcinoma is in all probability only apparent. Katz investigated all cases of primary cancer of the lungs in the autopsy records for sixty years at the Heidelberg Pathologic Institute. His table, showing the incidence of pulmonary cancers and of all cancers for the years 1906 to 1926, shows a relative as well as an absolute increase of bronchiogenic carcinoma.

#### FACTORS CAUSING INCREASED INCIDENCE

Since primary bronchiogenic carcinoma has shown an increased incidence in recent years, the question arises as to the factors which have been responsible. Many observers attribute the increase to the epidemic of influenza in 1918-1919. On the other hand, Kerley said that cancer of the lung has never been reported in Iceland, where the ravages of influenza have been exceptionally severe. Other authorities have said that the increase is due to industrial expansion, tarred roads,

a large number of death certificates, found that certain classes of laborers are especially liable to cancer of the lung. Among these are road workers, metal grinders, employees in gas works and persons engaged in the tobacco trade. Arkin and Wagner<sup>8</sup> stated that twenty years ago only 5 per cent of primary bronchiogenic carcinomas were diagnosed clinically, while today about 50 per cent are recognized during life. This would appear to show that better diagnostic methods have contributed to the increase in the number that are recognized and the consequent increase of the incidence of this type of tumor.

This brings me to the consideration of the data in table 1 on the nature of the increased incidence of carcinoma in general and of primary bronchiogenic carcinoma in particular in the veterans' group. The percentage relation of all carcinomas to all autopsies was 17.5 per cent in 1932 and 22.4 per cent in 1937, an increase of 28 per cent. The percentage relation of primary bronchiogenic carcinomas to all autopsies varied from 2.4 per cent in 1932 to 5.3 per cent in 1937, an increase of 120.8 per cent. Finally, the percentage relation of primary bronchiogenic carcinomas to all carcinomas varied from 13.8 per cent in 1932 to 23.4 per cent in 1937, an increase of 69.6 per cent.

The statistical data representing the relation of primary bronchiogenic carcinomas to all carcinomas are of importance, as they indicate the nature of the increased incidence. If the increased incidence were dependent on and due to an increase of all carcinomas, the percentage relation each year would be about the same and would be constant over a period of years. A graph showing the relation would be represented by a horizontal line. But, as seen in chart 1, the trend is definitely upward. It may therefore be concluded that the increased incidence of primary bronchiogenic carcinoma is absolute.

In order to confirm further the observation that the increase of primary bronchiogenic carcinoma is absolute, a study was made of the yearly incidence of cancer of two other inaccessible sites, the colon and prostate, from 1931 through the first half of 1937, and of the percentage relation of each of these two types of cancer to all carcinomas during the same period. It was found that there was little annual variation in the incidence of these two types of carcinoma and their relation to the total number of carcinomas. In other words, the incidence from year to year was fairly constant and related to the incidence of all carcinomas, as compared with the incidence of bronchiogenic carcinoma, which was not so dependent and the increase of which was considered absolute.

In addition to an absolute increase, an analysis of the data shows that there is also a relative increase of primary bronchiogenic carcinoma. In other words, the relative increase of this type of tumor in the veterans' population is dependent on a number of factors. One of these factors is the expansion of the facilities for the diagnosis and treatment of cancer in the Veterans Administration since 1930; the administrator authorized the establishment at that time of the Tumor Clinic at Hines, Ill., and subsequently of a number of such clinics in other cities. Thereafter the interest in cancer was accentuated, and the number of bronchiogenic carcinomas diagnosed ante mortem increased. In

Incidence of primary bronchiogenic carcinoma in veterans' group.

addition, when a pulmonary condition was suspected of being primary bronchiogenic carcinoma but was not diagnosed ante mortem, autopsy was performed and the condition then recognized; accordingly there was an increase in the number of carcinomas found at autopsy.

Still another cause of the relative increase of primary bronchiogenic carcinoma is the age distribution of the veterans' group. It is noted that from 1930 to 1937 the average age of all veterans was from 40 to 47. This

period included the ages at which the largest number of primary bronchiogenic carcinomas was found. Thus in 118, or 85 per cent, of 138 cases in which a record is available as to the year of onset, there was evidence of onset between 1931 and 1936. Accordingly the increase of primary bronchiogenic carcinoma during the past few years has in part been due to the aging of the veterans.

DISEASES OF THE RESPIRATORY TRACT AS CAUSATIVE FACTORS IN CANCER OF THE LUNG

In 1920 Winternitz actually prophesied that an increase of primary bronchiogenic carcinoma would follow the influenza epidemic, because he found that influenza and influenza-pneumonia frequently resulted in metaplasia of the bronchial epithelium and a proliferation of the young cells to the extent that it was difficult to distinguish the cellular condition micro-

atypical cell regeneration, metaplasia and cell nest formation, indicating a tendency for this disease to cause irregularities of cell growth.

In this connection I wish to quote the opinion of Wells,<sup>11</sup> who maintained that if the increased incidence of cancer of the lung is a sequel of influenza, the increase should be transitory, but that if it is the result of industrial expansion and irritation of the respiratory tract by noxious chemicals and gases, or if it is due to dust from tarred roads, the increase may become permanent and significant.

The relation of pulmonary tuberculosis to the inception of cancer has also been the subject of considerable discussion among observers. Ewing is an exponent of the view that pulmonary tuberculosis is a factor in the causation of primary bronchiogenic carcinoma. Davidson<sup>10</sup> stated that the association of cancer of the lung and tuberculosis is a question which has given

scopically from neoplasm. The studies of Barron, Fried and Moise showed an increase of cancer of the lung dating from the influenza epidemic.

On the European continent data on the relation of influenza to cancer of the lung are conflicting and are not as clear cut as those shown by the American investigators. The observations of Duguid<sup>9</sup> in Great Britain show a somewhat irregular increase but do not suggest an obvious relation of cancer of the lung to the influenza epidemic of 1918. However, the postmortem statistics of the London Hospital indicate an increase of cancer of the lung.

Shuster, as quoted by Davidson,<sup>10</sup> submitted the following arguments in favor of the idea that influenza is a predisposing cause of pulmonary carcinoma: (1) the coincidence of epidemics of influenza and the increase of lung cancer; (2) the special tendency in influenza for chronic inflammation to persist, with pulmonary fibrosis and bronchiectasis, and the fact that these processes occur in cancer of the lung in varying degrees, and (3) the observation in lungs affected by influenza of

rise to a certain amount of discussion. In a study of the Brompton Hospital series of 107 cases in which autopsy was performed, only seven persons, or 6.5 per cent, were found to have definite evidence of tuberculous disease and primary bronchiogenic carcinoma.

Other diseases of the respiratory tract are mentioned by various observers as preceding the onset of cancer of the lung and as being factors in the causation of this type of tumor.

In analyzing the available data in the literature with regard to the relation of preceding disease of the respiratory tract to primary bronchiogenic carcinoma, I may state that there is a suggestion that certain pulmonary diseases have in recent years appeared more frequently and that, as a result of their irritating influence on the bronchial mucosa, cancer of the lung has developed in susceptible persons.

In an effort to learn whether or not certain preceding diseases of the respiratory tract were factors in the inception of primary bronchiogenic carcinoma in the veterans' group of 138 cases, a study was made of the clinical records in these cases, including a review of

the medical history previous to the patient's admission to military service. This study revealed that eighty-one, or 58.7 per cent, of the men gave evidence of one or more preceding diseases of the respiratory tract which caused irritation of the bronchial mucosa, with a possible proliferation of the lining cells and resulting metaplasia. The diseases which were most frequently reported were influenza, bronchitis, pneumonia, pleurisy, pulmonary tuberculosis, bronchial asthma and the residuals of warfare gassing. These conditions existed alone or in various combinations; the number and percentage of cases of each disease in the 138 cases may be found in table 2.

It is believed that the incidence of preceding diseases of the respiratory tract in this group of cases is sufficiently great to be suggestive that such conditions constituted one factor which may have led to the inception of primary bronchiogenic carcinoma. It is realized, of course, that other causative factors are involved, such as heredity, individual predisposition and perhaps tissue or organ susceptibility; but these factors may be

fourth, were from 30 to 39, and twenty-six, or approximately 19 per cent, were from 50 to 59. The youngest was 21 and the oldest 74 at the time of the inception of the tumor; the average age at the time of onset was 45.

An analysis of these data shows that the veterans give evidence of a younger age incidence for the onset of primary bronchiogenic carcinoma than is noted in civil life. This is due to the fact that with them one is dealing with a group of men, of whom the largest number are in the younger age groups. These data would seem to indicate that one may expect to see a larger number of patients with primary bronchiogenic carcinoma in the veterans' group in the immediate future.

#### OCCUPATION

The question whether certain occupations are a factor in the inception of primary bronchiogenic carcinoma is controversial. Rosedale and McKay,<sup>12</sup> in a study of fifty-seven cases of primary bronchiogenic carcinoma, found that in forty-three, or 75.4 per cent, the patient

regarded as predisposing in comparison with the diseases of the respiratory tract, which may be considered exciting factors. Suffice it to say that when these factors become operative at the cancer age primary bronchiogenic carcinoma was a result.

#### AGE INCIDENCE

Age is one of the factors concerned with the onset of primary bronchiogenic carcinoma. Its part in the development of this type of neoplasm is similar to its role in connection with carcinoma in general. There evidently is a certain period of life which is characterized by abnormal processes of one kind or another, predisposing to the onset of cancer; at this period a precipitating or exciting factor may conduce to the actual development of the neoplasm.

Considerable work has been done on the age incidence of primary bronchiogenic carcinoma. The data of a number of observers have been compiled and have been consolidated in table 3. These data show that of a total of 1,814 primary bronchiogenic carcinomas, the largest number had their onset in the age period 50 to 59, the second largest number in the age period 40 to 49 and the third largest number in the age period 60 to 69. As far as can be learned from the statistics the youngest patient was 13 and the oldest 89 at the time of onset.

In table 4, which gives the age at the time of onset of primary bronchiogenic carcinoma of 138 veterans, it is shown that sixty-seven, or almost one half, of the veterans were from 40 to 49; thirty-five, or one

was employed in an occupation requiring exposure to dust or other irritating atmospheric factors. The authors said that such exposure may be a factor in producing chronic irritation of the bronchial epithelium resulting in protoplasia and metaplasia. Simons<sup>3</sup> stated that until further information is obtained on the rela-

tion of occupation to the inception of cancer of the lung, industrial hazards cannot be accorded any etiologic significance except as they involve chronic irritation of the lungs.

In this study, it was found that fifty, or 36 per cent, of the 138 patients gave a history of being connected with occupations or industries in which there was a

12. Rosedale, Raymond S., and McKay, Donald R.: A Study of 57 Cases of Bronchiogenic Carcinoma, *Am. J. Cancer* 26: 493-506 (March) 1936.

possibility of irritation and traumatization of the respiratory tract. The fact that so large a percentage had been engaged in occupations which caused them to be exposed to chronic irritation of the respiratory tract is suggestive that such occupations may have played a causative part in the inception of the primary bronchiogenic carcinoma.

#### HEREDITY

Whether or not heredity is a factor in the inception of primary bronchiogenic carcinoma is still questionable. Members of certain families do show a predisposition to cancer. On the other hand, cancer is such a widespread disease that one would expect to find it in some generations of many families. One might therefore be inclined to the view that it is hereditary in origin. A study of the clinical records of 138 cases showed that in twenty-one, or 15.2 per cent, there was evidence of a hereditary, familial or combined hereditary and familial history of cancer.

Hospital histories are frequently lacking in data on the hereditary or familial aspects of the disease involved. Accordingly it is not believed that the information on heredity noted in the histories in these cases is complete or does justice to this phase of the subject, so that no definite conclusion may be reached from the available information.

#### COMMENT

It has been the observation of physicians of the Veterans Administration that the incidence of primary bronchiogenic carcinoma in the veterans' group has been increasing at an accelerating rate during the past few years. The question has been asked What factors are responsible for the increase?

In order to obtain information which would throw light on this problem it was decided to make a study of the autopsy material of the Veterans Administration. Accordingly a careful review was made of 7,398 post-mortem protocols. These reports were based on autopsies performed between 1927 and the first half of 1937. A total of 160 records of bronchiogenic carcinoma were found in this material, of which 138, with the accompanying clinical records, were studied intensively.

This study revealed the fact that a definite increase of the incidence of carcinoma in general and of primary bronchiogenic carcinoma in particular has taken place. The percentage relation of all carcinomas to all autopsies increased by 28 per cent from 1932 to 1937; for the same period the percentage relation of primary bronchiogenic carcinomas to all autopsies increased by 120.8 per cent and the percentage relation of primary bronchiogenic carcinomas to all carcinomas by 69.6 per cent.

Of the increases just mentioned, that pertaining to the relation of primary bronchiogenic carcinomas to all carcinomas is important, as from a statistical standpoint it definitely shows that the increase is absolute. If the increased incidence of bronchiogenic carcinomas were related to and dependent on an increase of all carcinomas, the percentage relation each year would be about the same and would be constant over a period of years. A graph showing the relation would be represented by a horizontal line, whereas the actual graph shows a definitely upward trend. The statistical inference therefore is that the increased incidence of primary bronchiogenic carcinoma is absolute.

In order to find further support for the observation that the increase of primary bronchiogenic carcinoma is absolute, a comparative study was made of the annual

incidence of carcinoma of the colon and of the prostate and their percentage relationships to all carcinomas from 1931 to the first half of 1937. For this purpose these two types of carcinoma may be considered inaccessible and may be placed in the category with primary bronchiogenic carcinoma.

It was found that the incidence of these two tumors and their relation to all carcinomas were comparatively constant from year to year. This indicates that the incidence of carcinoma of the colon and of the prostate was related to the incidence of all carcinomas, as compared with the incidence of cancer of the lung, which was partly so related and was increasing. Accordingly, these data lend weight to the observation that the increase of primary bronchiogenic carcinoma is in part absolute.

When the increase of the incidence of primary bronchiogenic carcinoma in the veterans' group was found to be absolute, the question arose as to what factors were responsible. Accordingly attention was focused on preceding diseases of the respiratory tract, the reports of a number of observers who had made a study of this problem being kept in mind. It was found that in eighty-one, or 58.7 per cent, of the 138 cases there was evidence that acute or chronic diseases of the respiratory tract of various kinds, either singly or in combination, had been present prior to the inception of the neoplasm. The presence of chronic diseases of the respiratory tract in so large a percentage of these cases was suggestive that they played a part in the inception of the tumor in persons with predisposing heredity and age and increased tissue susceptibility.

Further study of the problem revealed that 36 per cent of the patients had been engaged in occupations which were accompanied by exposure to irritation of the respiratory tract and traumatization of various kinds. It was thought that such exposure may have had a part in the inception of the tumor in the veterans' group.

In a study of the statistical data in the 138 cases it was found that there was a steady rise in the number of carcinomas of all kinds as well as in the number of bronchiogenic carcinomas from 1931 to 1937. This rise coincided with the increase of the average age, which was 41 in 1931 and about 47 in 1937; in other words the rise began when many of the veterans entered the cancer age period and has continued since then. Accordingly the factors which have their fruition at or during the cancer age period and which contribute to the inception of malignant neoplasm have been playing a similar part in the cases under consideration and have been responsible for the relative increase of the incidence of primary cancer of the lung.

Finally, it was noted that the increase of the number of bronchiogenic carcinomas received impetus after the expansion of the facilities of the Veterans Administration for the diagnosis and treatment of cancer in 1930. It is believed that the establishment of the Cancer Clinic at Hines, Ill., and of the auxiliary clinics in other sections of the country stimulated interest in the diagnosis and postmortem study of primary bronchiogenic carcinomas, with resulting increased recognition of the existence of the tumor of the lung. This increased recognition may be cited as a factor responsible for the increased relative incidence of cancer of the lung in the veterans' group.

The factors which have been described as contributing to the absolute and relative increase of primary

bronchiogenic carcinoma in the veterans' group may be said to play similar parts in the increase of cancer of the lung which has been noted in recent years in the civilian population.

#### CONCLUSIONS

1. The incidence of primary bronchiogenic carcinoma in the veterans' population has been increasing during the past few years. This increase is both absolute and relative.

2. The absolute increase of this type of tumor is unrelated to the increase of carcinoma in general. The factors which may be responsible for the absolute increase of cancer of the lung are the large percentage of preceding diseases of the respiratory tract and the fact that a comparatively large number of the persons in this group were in occupations which were accompanied by exposure to irritations of the respiratory tract and traumatizations of various kinds.

3. One of the factors causing a relative increased incidence of bronchiogenic carcinoma is the added interest in cancer on the part of the physicians of the Veterans Administration, resulting in an increase of the number of cancers of the lung diagnosed ante mortem. In many of the cases in which carcinoma was suspected but was not definitely diagnosed ante mortem, postmortem examination was made; hence the increased incidence of this type of tumor in autopsy statistics.

4. Another factor which may be held responsible for the relative increase in the incidence of cancer of the lung is the entrance of the veterans' group into the cancer age period.

5. A comparative study of the data on the incidence of cancers of the lung according to age in the civilian population and in the veterans' group shows that the largest number of civilian patients are older than the veterans. One may therefore expect that as the veterans grow older an increasing number of primary bronchiogenic carcinomas will be seen among them.

#### ABSTRACT OF DISCUSSION

DR. MAX CUTLER, Chicago: The conclusions which Dr. Matz has drawn are in agreement with the opinions generally expressed by other students of the subject. There can be little doubt that the increase in the incidence of pulmonary cancer is not apparent but real. This fact raises implications concerning the etiology of bronchiogenic carcinoma which are interesting and possibly important. The increase in the frequency of cancer of the lung during the last few decades appears in all statistics including those from America, England, Germany, Austria and Switzerland. It is interesting to note that the increase in the frequency of this disease was not observed in all places at the same time. In Riga, for example, an increased incidence was noted as early as 1900 (Hanteln) and reached its peak in 1916 (Brandt). In Oslo and Innsbruck, on the other hand, a marked increased incidence has not been observed even in recent years. In Berlin, Hamburg and Basel a slightly increased incidence was noted in 1900 but did not become pronounced until recently, whereas in Basel the peak was reached in 1914 and no further increase has been observed since. In considering the possible causes for the increased incidence of cancer of the lung several questions arise, among which hereditary predisposition at once requires serious attention. The experiments of Maud Slye indicate that certain strains of mice are more prone to development of cancer of the lung than others, and Clara Lynch was able to produce cancer of the lung more rapidly and more frequently by application of tar in certain inbred strains than in other strains. Those experiments seem to indicate that the development of cancer of the lung after painting of the skin with tar is independent of the development of cancer in this area. Thus a special predisposition of the lung to the development of carcinoma under these con-

ditions is suggested. The etiologic relationship between certain irritating agents and cancer of the lung was demonstrated dramatically in the Schneeberg cancers which developed among miners in Saxony. A combination of arsenic and radium emanation contained in the dust proved to be the causative factors. In connection with the possible relationship of influenza to cancer of the lung, it is interesting to note that spontaneous occurrence of lung tumors among rats, which are also prone to other infectious lung diseases, were not observed. The evidence which has accumulated on this subject renders it difficult to escape the suspicion, if not the conclusion, that certain cell stimulating agents—infections and chemicals—probably play an important role in the etiology of cancer of the lung and that the increase in the incidence of this disease may possibly be related to some of these factors.

DR. PHILIP B. MATZ, Washington, D. C.: There is nothing I wish to add except to repeat that about 15.2 per cent of the group studied gave evidence of a hereditary or familial history of cancer. Although this figure seems high it should be considered the minimum for the group, as it is often difficult to obtain the familial and hereditary data from the clinical histories.

### SUBPIAL RESECTION OF THE CORTEX FOR FOCAL EPILEPSY

#### FURTHER OBSERVATIONS

LEONARD T. FURLOW, M.D.

ST. LOUIS

In 1909 Horsley<sup>1</sup> described a method of excision of an area of motor cortex for the relief of violent athetoid and convulsive movements of an upper extremity. This consisted in splitting the pia lengthwise over the center of the convolution to be partially excised, gradually pushing the pia back to the extreme edge of the sulcus on either side, and then removing the necessary amount of the convolution. In 1935 Sachs<sup>2</sup> reported experiences with this subpial resection of the cortex in the treatment of focal epilepsy and athetosis. The actual procedure he called the Horsley operation. Since that time there have been other cases in which it was thought that the procedure was indicated and, having found it to be of definite value, I am making this report.

In the paper<sup>2</sup> mentioned, eleven cases in which this operation had been done were reported. Two of the patients suffered from athetosis, five had a definite history of preceding severe trauma to the head, and in three the cortex was normal both grossly and microscopically. In the final case the convolution in which the motor arm center was located looked broader than normal and on microscopic study showed some gliosis, but no tumor. In three of the cases in which there was a history of preceding trauma the actual starting point of the convulsion, as determined by galvanic stimulation, was apparently not involved by any scar or adhesions, so that an accurate subpial resection could be carried out.

Up until the time of that report<sup>2</sup> and since, my associates and I have attempted to select and classify carefully all cases of focal epilepsy coming under our care. Observation over a number of days, if necessary, is carried out, and every effort is made to have one or

From the neurosurgical service of the Washington University School of Medicine and the Barnes and St. Louis Children's hospitals. Read before the Section on Nervous and Mental Diseases at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

more convulsions observed by either a member of the staff or an experienced nurse, to verify the statement of the patient or the family that the seizures are focal. Exhaustive studies are made to determine or rule out the presence of a cerebral tumor, and naturally all cases of tumor have been excluded from this study. A careful evaluation of the patient's mental status is made, for it is our feeling that nothing can be accomplished by operations on patients who have extensive cortical degeneration. The post-traumatic cases are divided into two groups, those in which so widespread a trauma has occurred that a massive excision of a cortical scar is necessary, and those in which a more focal injury has occurred with a smaller area of scar. In the latter group of cases, if it is at all possible, we prefer to do a subpial resection rather than a removal of the scar with the electric knife.

The actual technical procedure is not difficult. Unless the patient absolutely refuses, the operation is done under local anesthesia for, with general anesthesia, much more electric current is required for cortical stimulation. After the dural flap has been reflected, careful examination of the exposed cortex is made. If nothing abnormal is found, stimulation with a unipolar galvanic electrode is done. The amount of current used is the minimal amount necessary to produce a slight contraction of the exposed temporal muscle, and, using this current we carefully and unhurriedly define the area of exposed cortex which when stimulated will reproduce the focal convulsive movements or sensory seizure. Then a nick is made in the pia in the center of the convolution, a small dural elevator is inserted beneath the pia (fig. 1), and it is incised with a pointed knife. Then with cotton pledgets the pia is gently rolled back to the edges of the sulcus (fig. 2), and with a brain spoon the necessary amount of convolution is removed (fig. 3), care being taken to stay inside the pia. There is no bleeding, and the area originally outlined is removed with exactness. It should be emphasized that the removal must include all areas which, when stimulated, produce the movement or sensation sought, for in several of the early cases it was necessary to do a secondary operation and remove more cortex because the original removal had not been extensive enough.

We now have sixteen cases in which this procedure has been carried out. Eleven of the patients had focal epilepsy with motor phenomena, three had attacks which combined motor and sensory phenomena, and two had violent athetotic arm movements.

The immediate postoperative course is interesting in view of the recent discussions as to the function of the so-called motor and premotor cortex. All areas of removed cortex have been studied by Dr. O'Leary of the Department of Cytology of the Washington University School of Medicine, and in every instance in which we have removed area 4 a spastic paralysis has occurred. We have never seen an initial period of flaccidity as Fulton<sup>3</sup> has observed, and the recovery of motor power after operation has conformed to the original observations of Horsley<sup>1</sup> and of Leyton and Sherrington,<sup>4</sup> recently reviewed by Walshe.<sup>5</sup> The

proximal joints have always recovered first, movements of the digits later, and finer movements of the fingers never return completely, though all patients have been able to return to their former occupations.

The ultimate test of the value of any method of treatment must, of course, be based on the clinical results obtained. It is quite generally recognized that the evaluation of procedures used in the treatment of any form of epilepsy is very difficult, for one can only say that the epileptic patient is cured when he dies years later from some other cause and remains free of convulsions up to the time of death. In spite of this difficulty, however, attempts at evaluation are necessary to decide whether or not a procedure is worthy of continued use, and such an attempt will be made for the Horsley operation on the basis of the results which we have obtained up to this time.

In the series of sixteen cases of subpial resection (table 1) there have been two deaths. One (patient 1<sup>2</sup>)

Fig. 1.—Method of freeing the pia.

died of an infection following laminectomy for posterior root section about two weeks after the subpial resection. The other patient developed an extradural postoperative clot and in spite of the removal of the clot died forty-eight hours after the original operation. The mortality rate for the series is 12.5 per cent.

So far as we have been able to determine, seven, or 43 per cent, of the patients have had no recurrence of convulsive seizures for periods ranging from four to twenty-three years. Thus we might claim a 43 per cent "cure." However, we still adhere to the definition of a "cure" for epilepsy as previously given.

In six cases there has been a recurrence of convulsive seizures, but in five instances the convulsions have been less severe, and every patient has been able to resume his former occupation. In three of these cases the attacks before operation were definitely jacksonian as to origin, but with the spread of the convulsion unconsciousness developed. Since operation, with one exception, the attacks which recurred have remained focal and consciousness has been retained.

In one case there has been no improvement, in that the attacks occur about as often as before operation and are just as severe. This case is an excellent example of poor selection, as the following brief summary will show:

Ten years before the entry of L. T. O., a man aged 23, admitted Jan. 24, 1938, his mother noticed a twitching of the muscles around the right corner of the mouth. The patient

hours, however, but for about ten days after operation there was some speech disturbance, chiefly in the enunciation of labials and sibilants, especially those occurring at the end of a word.

The patient was discharged on the thirteenth postoperative day and up to that time had had no more attacks. However, since discharge he reports by letter that both major and minor attacks have recurred and are about as frequent and severe as before the operation.

In the first place it was questionable, at least to some members of our staff, whether this case was one of true focal epilepsy. The minor attacks seemed purely subjective for no twitching was visible, and in the major attacks the spread was so rapid that it closely resembled general epilepsy.

In the second place the motor speech area, which of course could not be removed, seemed as much a focal

Fig. 2.—The convolution completely freed after the pia arachnoid has been pushed back with cotton pledgets.

was not aware of this twitching, nor was it noticed by other members of the family or by friends. This continued at intervals of two or three months for three years, when, without warning, the patient had an attack which began with drawing of the mouth to the right, but the attack spread very rapidly to become a generalized convulsion with loss of consciousness and ensuing stupor. Similar attacks recurred at frequent intervals, and three years before admission a left cerebral craniotomy was carried out elsewhere with no postoperative improvement.

TABLE 1.—Subpial Resection of Cortex

Diagnosis	Number	Deaths	"Cured"	Improved	Unimproved
Athetosis.....	2	1	1		
Focal epilepsy.....	14	1	7	5	1

The major attacks at the time of admission occurred about once each week and there were numerous minor attacks in which the patient was unable to speak and felt a twitching about the right corner of the mouth. However, this twitching could not be seen by the examiner.

Encephalography gave no evidence of a tumor nor could any other focal lesion be demonstrated. The attacks promptly recurred after encephalography. It was thoroughly explained to the patient that the results were uncertain because of the proximity of the motor speech area to the motor face center, but he was anxious for any procedure offering a chance of relief, so craniotomy was done under local anesthesia. With galvanic stimulation an area was found which produced movements of the right side of the face, jaw and throat. The patient said that this was identical with his minor attacks. A subpial resection of this area was carried out, and immediately following operation there was a slight cortical type of right facial weakness. This disappeared after twenty-four to forty-eight

8	6	2	1	1	5	1

point as the face center, so it was doubtful whether removal of the face center alone would help. The subsequent course has proved that conservatism would have been the wiser policy.

In reviewing these cases it is of interest to determine the result obtained in the eight cases in which there was a perfectly normal cortex with no history of preceding trauma (table 2). Three of these are included in the

Fig. 3.—Removal of the convolution after the pia arachnoid has been pushed back. This is an absolutely bloodless procedure.

previous report<sup>2</sup> and there have been five additional cases since that time. Of these eight patients one died shortly after operation, so that the mortality rate is the same as for the entire series, 12.5 per cent. In one case, already cited, no improvement occurred. Of the remaining six patients, one has been entirely free from

attacks for fifteen years and the other five have been able to resume their former occupations. In all cases the postoperative attacks have been less frequent and severe, and in only one has there been a progression to a generalized convulsion, and whereas this patient had twelve grand mal seizures in the year before operation he has had only two in the twelve months period since operation.

It is very important that these patients be given careful instructions as to the continuance of sedative drugs after operation. We use phenobarbital in small doses in every instance for many months even though there is no recurrence of attacks. The dosage may usually be greatly reduced as compared to the amount taken preoperatively, but several of our patients have had attacks only after disregarding orders and omitting medication.

One may only speculate as to future developments in this procedure. Even a casual comparison between this and the former report<sup>2</sup> will show that the results now are statistically less impressive than at that time. It is our feeling that this holds true of many methods of treatment, especially those dealing with epilepsy; viz., the longer the period of observation the lower the percentage of cures. The fact that the paralysis produced after cortical excision is only temporary is highly suggestive that motor innervation comes, at least in part, from adjacent convolutions, and we may not have been radical enough. It is our hope that studies of the electrical potentials of the exposed brain, such as we are now carrying out in a routine manner, will give a better understanding of the underlying etiology and pathology of epilepsy, and thereby assist in improving the therapy.

#### SUMMARY

In sixteen cases in which a subpial resection of an area of cortex (Horsley operation) has been done there have been two deaths, giving a mortality rate of 12.5 per cent. Seven patients have been, up to the present time, entirely relieved of attacks. Six patients have shown very definite improvement. In one case there has been no change.

#### ABSTRACT OF DISCUSSION

DR. R. G. SPURLING, Louisville, Ky.: I have done subpial resection on parts of the true motor cortex in which disease was not obvious in three instances. In one there has been complete relief of all convulsive phenomena for four years and in another great improvement, while in the third the result has been indifferent. I should like to ask whether all the excised tissue has been studied with serial sections. It must be remembered that most of the true motor cortex, area 4, in human beings, particularly the lower half, is folded into the sulcus. It seems to me therefore that it would be a difficult surgical feat to limit the excision sharply to area 4 without considerable damage to area 6. Unless Dr. Furlow can demonstrate histologically with serial sections that the resection does not encroach on area 6, I do not feel that he has sufficient evidence to challenge Dr. Fulton's observations on flaccidity and spasticity.

DR. LEONARD T. FURLOW, St. Louis: In the cases reported there was a rather prolonged preoperative period of treatment with drugs, and only after it was determined conclusively that the condition was not controlled by drugs was the patient submitted to operation. In regard to Dr. Spurling's question as to the histologic studies of the specimens removed: Serial sections were examined by Dr. O'Leary of the department of cytology, who, we feel, is much more capable of expressing a definite opinion than are we of the department of neurosurgery, and he assures me that there was an accurate excision of the motor cortex.

## THE MANAGEMENT OF EXTERNAL INTESTINAL FISTULAS

CLAUDE F. DIXON, M.D.

ROCHESTER, MINN.

AND

JOEL L. DEUTERMAN, M.D.

Fellow in Surgery, the Mayo Foundation

ELGIN, ILL.

Intestinal fistula may be defined as an abnormal communication between a portion of the intestinal tract and a hollow abdominal viscus (internal fistula) or between a segment of the intestine and surface of the body (external fistula).

#### CLASSIFICATION AND ETIOLOGY

From an etiologic standpoint, intestinal fistulas may be placed in two general groups: (1) those which are intentionally established by such operations as colostomy, enterostomy or appendicostomy and (2) those which are produced by some pathologic process or by trauma, for example actinomycosis, tuberculosis, regional enteritis, a malignant condition, gunshot or penetrating wounds or surgical accidents. The fistulas which arise as a result of inflammatory disease are most frequently the sequelae of appendicitis, diverticulitis and pelvic inflammatory processes. Similar classifications have been suggested by Rigby<sup>1</sup> and Coffey.<sup>2</sup>

In a review of 109 cases of fecal fistula collected from the records of Johns Hopkins Hospital from 1891 to 1931, Lewis and Penick<sup>3</sup> made the following classification: (1) subsequent to appendicitis (44.9 per cent), (2) associated with other infections (12.8 per cent), (3) attributable to malignancy (2 cases), (4) resulting from trauma and nonoperative measures (5 cases), (5) following operations (19.2 per cent).

It has been estimated that approximately 4 per cent of cases of appendicitis are followed by fecal fistula. Many such fistulas communicate with the cecum. In recent years it has been observed that a considerable number of fistulas follow removal of an inflamed appendix in cases in which terminal ileitis or typhlitis is present. A fecal fistula may follow evacuation of an appendiceal abscess in cases in which it does not seem feasible to remove the remnant of appendix at the primary operation. A fecalith in the remaining portion of the appendix may be responsible for the formation of such a fistula. There have been strong arguments both for and against inversion of the appendiceal stump. According to experience at the Mayo Clinic, inversion of the stump by means of silk ligatures has been satisfactory, for we have not observed a case in which the edematous cecal walls have become necrotic and have sloughed, as has been reported in some articles. Lewis and Penick<sup>3</sup> mentioned only five instances in which fecal fistula followed inversion of the appendiceal stump in several thousand cases in which appendectomy was performed at the Johns Hopkins Hospital. Of course, especial care should be exercised

in suturing the inflamed intestinal walls. Catgut sutures are employed if definite typhlitis is present.

The drain employed at an abdominal operation may be responsible for postoperative fistula. However, practically every writer on the subject has concluded that the use of drainage material is definitely indicated under such conditions as that of appendical abscess. Hard rubber drains may produce pressure necrosis of a portion of intestinal wall and give rise to fistula. A fistula is likely to follow any extensive operation in the presence of infection or potential infection. Retained gauze sponges, unabsorbed ligatures, parts of surgical instruments or fecaliths may be the cause of failure of a surgical wound to heal.

Incomplete removal of a diseased portion of intestine may be followed by a postoperative sinus or such a condition may ensue from disturbance of the blood supply or other operative trauma. Injury to the duodenum giving rise to fistula may occur during removal of the right kidney. W. J. Mayo<sup>4</sup> reported three such cases, in all of which there was fatal issue. He called attention to the danger of blindly attempting to control hemorrhage with heavy forceps. Injury to the duodenum may occur during operation on the gall-bladder, in the presence of anomalies or extensive adhesions which require considerable dissection. A fistula sometimes develops after repair of a hernia and following pelvic operation, especially if the latter is concerned with inflamed adnexa.

A number of other causes of intestinal fistula have been recognized: Regional enteritis, affecting either the small or the large intestine, may produce fistula and in many instances a tract develops as a result of localized abscess following perforation of the diseased intestinal segment. Foreign bodies within the lumen of the bowel may be responsible for perforation and the production of fistula. Abdominal injuries, such as gunshot or stab wounds, may lead to formation of fistula as a result of some damage to the adjacent bowel or to its blood supply. Strangulated hernia may have a similar effect. A blow on the abdomen may cause injury to a viscus (for example, the retroperitoneal portion of the duodenum) even though the abdominal wall has not been penetrated. Congenital intestinal fistula is a rare sequence of failure of the vitello-intestinal duct to close.

#### SYMPTOMS AND CONSTITUTIONAL EFFECTS

The primary factor which determines the local and constitutional effect of the fistula is the segment of intestine involved. The nearer the opening in the intestine is to the pylorus, the greater is the power of the intestinal contents for digestion of the skin and the more profound is the constitutional effect from loss of electrolytes. The size of the fistulous opening is not as important as the amount of fluid that is lost, and these features are not necessarily comparable since large quantities of fluid may escape through a small opening in the duodenum while a huge colonic stoma may have comparatively slight local or constitutional effects so far as loss of fluid is concerned. As Kanavel<sup>5</sup> and Dixon<sup>6</sup> have shown, severe toxemia is produced

by loss of a large amount of the biliary and pancreatic secretion. Walters and Bollman<sup>7</sup> and Walters, Kilgore and Bollman<sup>8</sup> have shown that the same effects ensue from obstruction high in the intestinal tract; namely, there is an increase in blood urea and in the carbon dioxide combining power of the plasma and a decrease in the chlorides of the blood. If the fistula arises high in the intestinal tract, as in the duodenum or jejunum, there is usually marked irritation of the skin and excoriation as a result of the action of trypsin, which is secreted as trypsinogen and is activated by the enterokinase of the duodenal secretion. As much as 4 liters of fluid may be lost daily through such a fistula. The loss of gastric secretions alone results in alkalosis, while loss of the pancreatic secretions alone will tend to result in acidosis; in many cases the presence of a fistula diverts quantities of both to the surface.

#### DIAGNOSIS

The diagnosis of intestinal fistula usually is not difficult to make, although Baldwin<sup>9</sup> expressed the belief that the odor of infection caused by the presence of colon bacilli in the wound and that of fecal material discharged through a fistula might easily be confused by those not familiar with either condition. In some instances in which the opening in the intestine is minute and the amount of drainage small, a history of the passage of gas through the tract helps to establish the diagnosis or the taking by mouth of a dye such as carmine red may reveal whether the conclusions as to the presence of fistula are correct. Judd<sup>10</sup> suggested injection of an opaque medium into the sinus and plugging the opening. After this the patient is given a purge and subsequently the course of the substance is observed roentgenologically. If the medium appears in the bowel, the presence of an intestinal fistula is established. Purulent material mixed with the fecal discharge indicates infection or abscess about the sinus.

#### PROGNOSIS

Prognosis depends largely on the site of origin of the fistula; that is, the prospect of cure increases with proximity of the fistula to the anus. Colp<sup>11</sup> reported a mortality rate of 51 per cent in cases of duodenal fistula, with death occurring as early as three days subsequent to formation of the tract. Fistulas of the upper part of the intestinal tract do not heal spontaneously so often as do those which arise from the more distal segments of bowel. Lewis and Penick<sup>12</sup> reported a mortality rate of 8.9 per cent from surgical closure if the sinus tract was long and was lined by granulation tissue. MacLaren<sup>13</sup> found that 19 per cent of seventy-seven patients died following closure of sinuses that appeared after appendectomy but Deaver<sup>14</sup> reported a mortality rate of 49 per cent in 222 such cases in which operation was required. In ten of the 222 cases the sinus recurred but in most instances

healing was spontaneous. Rankin and Gorder<sup>14</sup> reported twenty-seven deaths in 264 cases in which 79 operations were performed, a mortality rate of 0.2 per cent.

#### MEDICAL TREATMENT

The aim of medical treatment is to prepare the patient for surgical closure of the fistula and to promote spontaneous closure by making conditions favorable for it. Many of the fistulas from the upper part of the intestinal tract can be caused to heal by this method.

A low residue, high caloric type of diet is employed. The site and character of the fistula must be established and the presence or absence of obstruction in the distal loop must be determined by roentgenologic studies. It is essential to detect and correct the chemical or fluid imbalance that so frequently occurs. The loss of chlorides and of water associated with fistula high in the intestinal tract can be compensated by intravenous administration of physiologic solution of sodium chloride and by use of salt in every possible way. If the proximal and distal loops can be recognized, loss of electrolytes will be prevented by collecting the fluid which drains from the proximal loop and injecting it into the distal segment of the intestine.

Excoriation of the skin which accompanies high intestinal fistula is the factor of greatest concern to the patient and, from the physician's standpoint, it is perhaps the most emergent condition at the beginning of the treatment. That this excoriation is extremely difficult to control is evidenced by the multiplicity of apparatus, devices and medication advocated for its relief. Constant suction seemingly gives the most nearly universal relief, as it removes the offending fluid before it attacks the cutaneous margin. A type of intermittent suction which gives considerable promise of being effective has been described recently by Tenopyr and Shafiroff.<sup>15</sup> If dressings are applied the offending fluid is retained in proximity to the skin and maceration is encouraged. A lighted hood keeps the skin dry, the lights may help to prevent action of enzymes on the skin, and a feature of importance is that a dressing is unnecessary. Frequent tub baths often are of material aid in relieving distress from excoriation.

CoTui<sup>16</sup> experimented with kaolin in the care of high intestinal fistula. The object was to remove trypsin by means of particles of kaolin which have a different electrical charge than that of the enzymes. According to experience at the clinic, a useful method of protecting the skin from the digestive action of enzymes is to place a suction tube through a wall that is built around the external stoma. This wall is made of adhesive tape and a paste composed of kaolin and water (fig. 1). Kaolin powder is used advantageously in this way. Occasionally an ointment made of kaolin and liquid petrolatum or kaolin and zinc oxide is effective in protecting the skin. First the abdominal wall is cleansed thoroughly with ether to remove all grease and to allow adhesive tape to stick to the tissues more firmly. In building the wall to which reference has just been made, the tape is applied about 2 inches (5 cm.) from the central opening; then the skin in

the enclosure is covered with powdered kaolin before any further fluid is discharged from the opening. The small amount of moisture in the skin is sufficient to cause a coating to form immediately and to protect the excoriated skin. Kaolin paste is then added at the periphery, forming a well, the bottom of which is the fistulous sinus. Sometimes, because of the extreme sensitiveness of the excoriated skin and consequent apprehensiveness of the patient, it is advisable to induce sleep for a few moments by giving thiopentothal intravenously. An opening is made in one side of the improvised wall and a fenestrated, soft rubber tube is so inserted that one end is outside and one is more or less inside the external stoma of the fistula. This permits aspiration of the fluid that drains forth without sucking the mucosa into the tip of the tube, thus plugging its lumen and possibly damaging the bowel. The solid cake of kaolin protects the epidermis. If the

Fig. 1.—Method of protecting skin by means of a suction tube inserted through a wall that encircles stoma.

cake of kaolin becomes undermined, it is removed, the area is cleaned and the process of caring for the fistula is repeated.

Plugging of the suction apparatus with mucosa or intestinal content is a handicap. Bohrer and Milici<sup>17</sup> inserted a fenestrated rubber tube a half inch in diameter into the fistulous tract to act as a reservoir, which is emptied by a smaller tube, thus preventing damage to the mucosa from suction and obviating plugging of the apparatus. This seemed to be a logical procedure and it was tried but the holes in the larger fenestrated tube became plugged. Potter<sup>18</sup> employed a Bradford frame on which the patient lay prone; in this method an opening through the frame permits drainage to take place into a bedpan. Some prolapse of the mucosa prevents the secretion from coming in contact with the skin. The frame is used at night and during periods of rest in the daytime; at other times continuous suction, which the patient manipulates, is available. The rubber tube is provided with a glass

tip so that plugging can be readily detected and remedied. To prevent plugging of the tube we have used a modified rectal drip apparatus; the escaping intestinal content is diluted by the saline solution thus provided and opportunity for occlusion of the suction tube is decreased.

Just recently we cared for a patient who had a fistula originating in the distal part of the jejunum; this had followed an abdominal operation performed elsewhere. There was marked destruction of the tissues surrounding the enteric stoma; the subcutaneous tissues had been digested and excoriation involved the entire left anterior abdominal wall. Obviously, the patient suffered constantly from excruciating pain and the use of a narcotic was required for relief. Since the denuded area was so large it seemed impracticable to attempt to build the usual kaolin dam or well; instead, a 10 per cent solution of tannic acid was sprayed over the tissues with an ordinary atomizer. Immediate relief followed. A tube was inserted a short distance into the fistula for the purpose of drainage and aspiration. The previous loss of fluids was made up by intravenous administration of saline and dextrose solution. Ten days later, surgical closure of the fistula was effected. Employment of tannic acid in such cases is suggested as a means of obtaining at least temporary relief from the distress which accompanies excoriation.

From the number of devices that have been advocated, it is evident that there is no method that is satisfactory in all cases. Erdman<sup>19</sup> treated a duodenal fistula by means of an apparatus for continuous suction, which he suspended from a semicircular rod designed by Pool. Ochsner<sup>20</sup> administered egg white orally and this was successful in lessening excoriation. Cameron<sup>21</sup> reported closure of a duodenal fistula in eleven days following continuous use of suction through a catheter placed in the opening of the fistula. Judd<sup>10</sup> and we have also treated several duodenal fistulas successfully by this method. Rees<sup>22</sup> obtained a satisfactory result by employment of dressings of commercial dried whole milk. Potter<sup>23</sup> advocated a solution of beef broth and tenth normal hydrochloric acid, with subsequent use of commercial peptone solution (Witte's) to absorb the enzymes. Warshaw and Hoffman<sup>24</sup> introduced hydrochloric acid directly into the sinus and kept the adjacent skin bathed in Witte's peptone solution. The injection of bismuth paste still has its proponents. Cushing<sup>25</sup> advocated a continuous bath and Ochsner<sup>26</sup> stated that a patient of his was saved by this method.

From time to time plugging of the external opening of the sinus tract has been advocated. This is definitely contraindicated in the presence of inflammation. The plugs have been made of various materials, ranging from ordinary gauze packing to tampons of iodoform gauze impregnated with 10 per cent camphorated oil to prevent saturation with secretion and to preclude

also the concomitant maceration. Chewing gum has been employed as a plug. Of course all such plugs are kept firmly in place by a sponge held in situ by adhesive tape or by a tight belt or binder. A few years ago we cared for a patient who had had a large enteric fistula for three years. Numerous attempts to secure closure by surgical intervention had been futile. He was induced to try plugging the stoma with chewing gum. After he had chewed four or five sticks of gum to extract the sugar, the gum was molded into a closed cone, the long end of which was inserted into the fistulous opening while the flange was compressed against the skin of the abdomen. In this manner the escape of enteric content could be prevented for many hours and the patient was afforded a degree of comfort he had not experienced in many years. Subsequently, this method has been employed many times in dealing with small fistulas. It is not proposed as a curative maneuver but it is mentioned as a means of preventing the escape of intestinal content. This accomplishes a double purpose: prevention of dehydration and of irritation of structures adjacent to the stoma. Any plan that will accomplish these objects obviously is of great aid in preparing patients for operation. According to Ochsner,<sup>26</sup> Reyband in 1827 advocated the insertion of wood or ivory plates into the fistulous opening and Kleybolte in 1842 described two leather disks connected by a thread which were used for the purpose. Recently Hartzell<sup>27</sup> has reported the use of a device which appears to be an elaboration of the plan of Reyband.

A large, flexible, rubber T-tube has been devised especially for use in the treatment of fistulas of the spur or hernial type. The original T-tube used by Koehler<sup>28</sup> utilized the entire tube. An advantageous modification has been effected by cutting the vertical limb horizontally, forming a gutter instead of a canal from that portion of the tube which is within the lumen of the bowel.

Fistulas which are distinctly more proximal to the anus (frequently referred to as "low" fistulas) heal spontaneously in from 39 to 88 per cent of cases; hence conservative measures should be tried for from six to twelve months before radical methods are employed. The length of time operation can be deferred judiciously is governed by the amount of inconvenience the patient suffers because of the fistula and by his general condition. Before undertaking conservative measures, the possibility of the existence of obstruction below the fecal stoma must be eliminated. Not infrequently a foreign body, such as a sponge, fecalith or a piece of unabsorbed suture material may be responsible for failure of the sinus to close. Epithelialization of the sinus tract can be prevented by employing silver nitrate. It has been reported that obliteration of the sinus tract has followed insertion and retention of a silver nitrate stick in the fistulous tract for a time. However, an ordinary gauze sponge frequently will accomplish the same result. If the opening of the sinus is large, it is advisable to anchor the plug firmly to the skin by string and strips of adhesive tape; an ordinary sea sponge can be used to cover the taped plug and produce pressure.

Before attempting to close a low fistula, the intestinal content should be evacuated thoroughly by means of

irrigation. Frequently it is possible to find the site of involvement by means of roentgenographic studies of the small intestine and colon. For three or four days prior to surgical intervention the patient should be given a nonresidue diet, and a saline laxative is to be employed to promote complete emptying of the intestine. The patient is encouraged to supplement the intake of fluid with sweetened fruit juices and to eat candy; both help to build up a carbohydrate reserve and thus to protect the liver and change the bacterial flora of the bowel. The patient who has an enteric fistula usually is fairly well vaccinated by the infectious process; consequently the antiperitonitis vaccine used as a routine in colonic cases might be eliminated in the preparatory treatment but as an extra precautionary measure it usually is employed.

#### SURGICAL TREATMENT

Jejunostomy of the Witzel type is perhaps the most conservative procedure in the surgical treatment of duodenal fistula. This places the affected segment of intestine partially at rest and permits administration of liquids and nourishment, and introduction of the duodenal secretion obtained by suction. In the absence of some such measure, the duodenal secretion tends to be lost by drainage to the outside.

W. J. Mayo<sup>29</sup> advised a transperitoneal approach for the repair of duodenal fistula resulting from injury received in the course of right nephrectomy. Deaver<sup>30</sup> stated that he had successfully repaired duodenal fistulas soon after their occurrence and that, in his opinion, delay was dangerous. In some cases he amputated the upper part of the duodenum and the pylorus and established a posterior gastro-enteric stoma. According to the experience of surgeons at the Mayo Clinic, application of constant suction frequently will bring about healing of a duodenal fistula. In a few cases in which the sinus persists, the delay affords a better opportunity for surgical intervention to be successful. The fluid balance should be watched carefully. Chemical imbalance in relation to the chlorides of the blood is compensated by giving sodium chloride intravenously or subcutaneously or by jejunostomy tube.

The surgical treatment of low intestinal fistula varies with the size and situation of the stoma. The presence of a spur or mucosa-lined tract almost invariably necessitates surgical intervention, which ranges from the application of spur-crushing clamps to simple closure or extensive resection of the intestine. The best procedure for treatment of a fistula which cannot be cured by medical means is one by which the sinus, and not infrequently the segment of bowel in which it arises, is removed. Lockhart-Mummery<sup>31</sup> said "Operations for closing fecal fistulas are not operations to be lightly undertaken unless one has had special experience. A serious difficulty in connection with these fistulas is that the exact anatomy of the bowel in relation to the abdominal wall cannot from the very nature of things be known with any exactitude." He also called attention to the necessity for intraperitoneal exposure to insure maintenance of the blood supply.

Simple closure of the fistula consists of inversion of the mucosal edges with two or three layers of chronic

catgut and suture of the skin. This procedure is not sufficiently radical to effect cure in every case and it is not advocated unqualifiedly by those who have had extensive experience in intestinal surgery. A more satisfactory procedure is closure by inversion of the mucous membrane and anatomic closure of fascial, muscular and subcutaneous layers.

When radical excision of the sinus and a portion of the bowel is indicated, it is our custom to make an incision which encircles the fistulous opening and extends well beyond the stoma, as this allows sufficient exposure. The sinus should be plugged to prevent spilling and the bowel is dissected free from the abdominal wall. The defect in the bowel is then repaired, either by resecting one or several loops of intestine or by merely closing the opening.

The sinus tract is isolated from the peritoneal cavity and from the incision by warm intestinal packs. A plan we have followed for several years is to apply a Payr clamp across the fistulous tract near the site at which closure is to be made or, if the fistula is small, a Kelly or Ochsner hemostat is used (fig. 2). Then the skin

Fig. 2.—Steps in closure of fistula.

and fat distal to or above the clamp are removed by excision with knife or cautery in close proximity to the clamp. After the fistula has been clamped, closure is begun. A through and through running suture is then placed immediately beneath the clamp. Next the clamp is removed. The second row of sutures is placed, a Cushing type of stitch being used to approximate the serosa over the first row of sutures. A third row of sutures may be employed for reinforcement. Then, if possible, a small patch of omentum is placed over the site of closure.

Attention has been called frequently to the importance of maintaining an adequate blood supply in these cases. The bowel should be cut at an acute angle with the mesenteric border, so that more is taken from the antimesenteric border than from the mesenteric side even if it is necessary to sacrifice normal intestine, for an ample blood supply is imperative for satisfactory and permanent closure.

If considerable manipulation of the viscera has been necessary an enteric stoma of the Witzel type, established proximal to the anastomosis, is often apparently a life-saving measure. Deaver<sup>30</sup> used one or more enteric stomas, according to indications.

29. Mayo, W. J.: Procedures Following Nephrectomy: I. The Transperitoneal Closure of Duodenal Fistulas Following Nephrectomy, *J. A. M. A.* 64:953-957 (March 20) 1915.

30. Deaver, J. B.: Gangrene of Appendix Resulting in Colic and Duodenal Fistulae, *Ann. Surg.* 79:605-606 (April) 1924.

31. Lockhart-Mummery, J. P.: Diseases of the Rectum and Colon. Baltimore, William Wood & Co., 1934.

Should several coils of the intestine be involved, resection of the affected segments may entail assumption of an unreasonable risk and the surgeon will display better judgment if he performs a short-circuiting operation by making a side to side anastomosis.

Unless there is considerable infection and formation of abscess about the sinus, closure without drainage of the peritoneal cavity is the rule. Lockhart-Mummery<sup>21</sup> placed a soft rubber drain down to the anastomosis and left the drain in situ for thirty-six hours. In the closure by layers, a portion of a rubber tube can be used outside the external fascia to act as a guide in case of drainage. The multiple retention sutures of the abdominal wall can be removed on or about the fourteenth postoperative day.

Extraperitoneal closure usually is employed for a temporary colonic stoma incidental to resection of a segment of intestine distal to the site of colostomy. An elliptic incision is made around the stoma at a sufficient distance from the opening to include the phlegmonous, gristly border of the skin. This incision is then continued through the fascial layers down to the peritoneum, but opening of the peritoneum is carefully avoided. The surrounding peritoneum is freed, so that there is ample room for the anastomosed bowel in the subfascial space. Since the intestine has not been divided completely, the mesenteric border is intact and the blood supply to the area of anastomosis is usually ample. The edges of the fistula are then trimmed, bleeding is controlled, and the bowel, which has been opened longitudinally, is sewed transversely with chromic intestinal catgut. Next, the layers of fascia are apposed and a split tube is inserted down to the fascia, thus insuring external discharge of drainage in the event leakage should occur through a long sinus tract.

Fecal fistula through the peritoneum following the Lockhart-Mummery type of operation performed because of a malignant condition of the lower part of the colon or rectum usually can be prevented by keeping the distal loop of intestine empty by means of irrigation. Should a sinus occur, daily irrigation frequently is sufficient to bring about spontaneous closure. A soft cotton plug, inserted into the stoma of the distal loop and anchored to the skin with a piece of string and adhesive tape, is an advantageous adjunct. A more radical measure, but one which is seldom necessary, is inversion and resection of the distal loop of the intestine.

#### POSTOPERATIVE CARE

Constant attention to many details is essential in the postoperative care of patients who have fistula of whatever origin. Immediately after operation the patient is allowed one-half ounce (15 cc.) of any "nonresidue" liquid every half hour, as tolerated. On the second postoperative day, 2 ounces (60 cc.) of liquid is given each hour; on the third postoperative day the amount of fluids is increased to 3 ounces (90 cc.) each hour; on the fourth postoperative day a full nonresidue liquid diet is permitted and the quantity is increased every third day until the tenth postoperative day, when a slightly modified general diet is provided. Daily, 2,000 cc. of 5 per cent dextrose in physiologic solution of sodium chloride is given intravenously or physiologic solution of sodium chloride is administered by infiltration.

Oral hygiene is important, especially if the patient is debilitated; he is encouraged to chew slices of orange or lemon and gum to prevent parotitis. When the

pulse rate is 72 or less per minute, 2 grains (0.12 Gm.) of thyroid extract is given three times daily as long as the beats are less than 100 a minute or until the patient is out of bed.

Liquid petrolatum is given twice daily, beginning on the fourth postoperative day. Three or 4 ounces (90 or 120 cc.) of olive oil is inserted into the rectum daily to prevent fecal inspissation or impaction. Irritant enemas are not given at any time. Vigilance with regard to this restriction is worthy of emphasis.

Restricted exercise is thought to be of distinct advantage and the patient is encouraged to turn in bed frequently and to move the arms and legs freely. He is also advised to take deep breathing exercises. The patient is permitted to sit up with his feet dangling over the side of the bed on the seventh postoperative day; the next day he begins to sit in a chair. Usually it is possible to dismiss the patient from the hospital sometime between the tenth and fifteenth postoperative days.

#### SUMMARY AND CONCLUSIONS

1. The most common cause of intestinal fistula is appendical infection. Many such fistulas are the result of nonspecific granulomas of the cecum and terminal part of the ileum.

2. Many fecal fistulas will close spontaneously within a few weeks. If the general condition of the patient warrants, many weeks should elapse before surgical intervention is undertaken.

3. Injury to the duodenum, with formation of fistula, is a serious and frequently fatal complication of renal and biliary surgical operation.

4. The mortality from repair of fecal fistulas ranges from 8.9 to around 50 per cent. Colp reported a mortality rate of 50 per cent from duodenal fistula occurring as a postoperative complication.

5. The prevention of epithelial excoriation with the use of some type of suction apparatus is a distinct advance in treatment.

6. If simple measures have been given a trial and are unsuccessful, some type of radical procedure should be instituted.

7. Careful preparation and postoperative care are essential.

#### ABSTRACT OF DISCUSSION

DR. GUNTHER W. NAGEL, San Francisco: The authors have presented their subject with their usual thoroughness and candor. Their observations are of special value because they are based on a large experience. The subject is not controversial, so that discussion is largely limited to emphasizing certain points. The subject may be divided into two main groups: prevention and treatment. Of these, prevention deserves special emphasis. In order to prevent intestinal fistulas, their cause must be determined. There are many causes, not all of which can be discussed at this time. In the experience of the authors, previous surgical procedures play an important part. In this group there must be considered again those which might have been prevented and those which arise in spite of one's best efforts. Certain lesions which are prone to result in fistulas if not recognized and properly handled are the group which are now classified as regional enteritis. This is a subject which has been widely discussed in recent years. In the treatment it is important to ascertain the approximate location of the fistula, the length of the tract, the underlying pathologic lesion and its extent, particularly if there is obstruction distal to the lesion. Preoperative methods occasionally result in spontaneous closure of the fistula. Important here are protection of the skin in high intestinal fistulas and replenishment of body fluids and chlorides. Suction is of course

important, and various cutaneous preparations are helpful. Such a simple measure as allowing air and light to reach the wound is occasionally neglected. In the operative procedure, two points must be emphasized: The loop of the bowel must be completely freed and any obstruction distal to the fistula must be relieved. If this is not done, failure will result. Intestinal fistulas may be catalogued and classified, but their treatment requires a high degree of surgical judgment and skill.

DR. ALTON OCHSNER, New Orleans: There are two points to which I should like to call attention as regards the conservative treatment of intestinal fistulas. The authors have emphasized the importance of determining the etiologic factor which is of the utmost importance. Most fistulas, however, unless there is a disease process, will heal spontaneously. A relatively simple measure is one I have been using the past year, which was accidentally observed following the diagnostic determination of the extent of a fistula. The introduction of the iodized oil into the fistulous tract in a surprisingly large number of cases will result in a healing of the fistula probably because of its bactericidal activity. It will be recalled that Beck's paste was used for a number of years and quite satisfactorily until the danger of bismuth poisoning was apparent. Iodized oil is perfectly innocuous. It not only determines the extent of the fistulous tract but also aids in the healing process. The authors have referred to the use of bronzing powder. In the clinic in which I work, bronzing powder is used extensively. Relatively recently a patient of mine quite ingeniously hit on a device of applying it which I think is unique. She takes ordinary aluminum paint—her father is in the paint business—and mixes it with cold cream until it has a buttery consistency, so that it can be applied easily to the surface of the skin. This makes an impervious covering which cannot be washed off.

DR. CLAUDE FRANK DIXON, Rochester, Minn.: Dr. Nagel emphasized the importance of attempting to determine the location of the fistula. This, I believe, is an important point and, as a rule, one can determine the segment of intestine from which the fistula arises. Dehydration is one of the greatest problems with which one has to deal in cases of high intestinal fistula. The work of Coller and his co-workers has indeed been of great value in the management of dehydrated patients. They have emphasized, as many know, the importance of supplying a sufficient amount of water so that the urinary output will be around 1,500 cc. a day. This is a good working rule. Their work also has been important in that they show so strikingly that 5 per cent dextrose solution without the addition of saline solution is the solution of choice in supplying liquid to these patients. Unless the blood chlorides are low there is, of course, no reason for the administration of sodium chloride. The care of the excoriated skin surrounding intestinal fistula is many times a great problem. I have used the aluminum paint mixture of which Dr. Ochsner has spoken. My experience has been that it has produced a marked burning sensation to such an extent in some cases that it had to be discontinued. The problem as I see it in dealing with enteric fistulas which require surgical intervention to effect closure is careful preparation of the patient, which means combating dehydration; second, the treatment of the excoriated skin, which in my service has been best managed by the kaolin dam, mentioned previously; and, finally, the use of intraperitoneal vaccine from thirty-six to forty-eight hours before operation.

**Psychopathic Wards in General Hospitals.**—The first psychopathic ward in a general hospital in America fulfilling the function of actual therapeutic treatment besides detention and observation was established at the Albany Hospital in 1902. "Pavilion F" was added to the hospital in that year "for the detention and care of persons afflicted with nervous and mental disorders," on the initiative of Dr. J. Montgomery Mosher, who directed its operation for many years thereafter. Since 1902, psychopathic wards or hospitals have been established in connection with general hospitals in many of the large municipalities. —Deutsch, Albert: *The Mentally Ill in America*, New York, Doubleday, Doran & Co., Inc., 1937.

## RED CROSS BLOOD TRANSFUSION PROJECTS

WILLIAM DEKLEINE, M.D.

WASHINGTON, D. C.

Following the example of the British and other European Red Cross societies, the American Red Cross has inaugurated a few blood transfusion services in this country.<sup>1</sup> The first one was started in Augusta, Ga., in May 1937 at the request and with the cooperation of the local physicians and staff of the Georgia State University Medical School and Hospital.<sup>2</sup> Other services have since been inaugurated, among them Baltimore, Paterson (N. J.), Memphis, Chattanooga and Jackson (Tenn.), Little Rock (Ark.), Lowell (Mass.) and Charleston and Aiken (S. C.). Washington, D. C., is about ready to start a campaign for enrolment. A dozen other cities are studying the plan, looking to its final adoption.

The project consists of enrolling volunteer donors who are willing to give blood without a fee for indigent or semi-indigent patients. It is not concerned with professional or paid donors and does not therefore interfere with established paid donor registries now operating in many of the larger cities and hospitals. After the project has been approved by the local physicians, hospitals and other groups concerned, the local Red Cross chapter conducts a campaign for enlisting the donors. They are examined, their blood is typed and if approved they are enrolled. Their names, addresses and telephone numbers are recorded and filed. Then, on receipt of a call from a hospital, the chapter calls a donor of the group requested and makes arrangements to have him transported to and from the hospital. The technical phases of transfusion are a matter for hospital regulation.

The primary objectives in organizing these projects are (a) to meet a widespread need for such services as evidenced by numerous inquiries and requests and (b) to develop a practical plan for operating them on an efficient and more or less uniform basis that does not obtain in volunteer donor services at the present time. Generally speaking, they are quite haphazardly organized and operated. Many communities and hospitals, particularly in the larger cities, have satisfactory registries for paid donors by enrolling so-called professionals, members of the hospital staff, medical students, firemen, policemen and other groups. Comparatively few cities, however, have adequate lists of donors for indigent patients. In most instances doctors appeal to relatives and friends of the patient or draft some one of the hospital staff whose blood has already been typed. As a last resort they sometimes have to make a public appeal through the press or over the radio.

These procedures may result in a rush of volunteers to the hospital, often necessitating grouping a large number before the right type is found; also in a hurried physical examination of the donor to determine his fitness as such. All this is tedious and time consuming and introduces elements of carelessness as well as undesirable heroics. It tends to place mistaken emphasis on the fundamentals of blood transfusion and the value of this important therapeutic measure.

1. Mimeographed Statements, Blood Transfusion Project, American National Red Cross.

2. Brooke, Mildred S.: Augusta Chapter Sponsors Blood Transfusion, Red Cross Courier, September 1937.

Relatives and friends should of course be used whenever possible, provided there is sufficient time for grouping and a careful examination. That is not always possible in emergencies and therefore places a heavy burden on the laboratory and hospital staff. If donors are grouped and examined in advance and the project skilfully managed, the service should become a valuable aid to physicians and hospitals. When blood donors are not readily available the patient often goes without transfusion. That has been brought to our attention by physicians on a number of occasions. Convenience of access and ease of administration multiply the use and effectiveness of any therapeutic measure many fold. Nowhere is this more evident than in blood transfusion.

This is well illustrated by the rapid growth of the British Red Cross service in London, which is perhaps the oldest established community-wide volunteer donor service in the world. It was started in 1921 from very small beginnings as a result of a call for a volunteer donor by one of the hospitals. Its founder, P. L. Oliver,<sup>3</sup> and his associates, recognizing the need for this service and its humanitarian aspects, initiated the plan. It has gradually grown over the years to a well organized and efficient service. In 1925 428 calls were received, in 1930 1,627. Last year 5,622 calls were answered, with an enrolment of 2,475 donors. It is used increasingly from year to year for more patients and for more forms of illness, largely because donors are readily available.<sup>4</sup>

A well planned and directed project of this kind will provide a valuable and convenient service. Physicians are using it now not only in emergencies as they occur in surgery and obstetrics but also in chronic anemias, blood dyscrasias and severe bacterial and chemical toxemias. While the value of transfusion in some of these conditions is still in question, the fact remains that physicians use it in critical illness if donors are available. Since there is a preponderance of illness among indigent and semi-indigent persons, there is greater need for transfusion among this class of patients.

The Red Cross is attempting to meet the need for volunteer donors in communities with a fairly large indigent population where there is no organized registry of this kind. The plan is inaugurated only after a careful study of local needs and facilities and the possibility of competent leadership. The point of view of the local physicians, hospitals and laboratory directors receives first consideration. It is left largely to them to determine whether the project shall or shall not be introduced. Their approval and whole-hearted cooperation is essential. Thus far nearly every study made of the plan in the cities that have adopted it was initiated by physicians or hospital officials and not by the Red Cross. We try to make clear that we are not promoting or urging adoption of the plan but rather that we are willing to organize the project through the chapters if and when the local medical profession and other groups concerned approve and actually want it. We have no other motive than to make this important therapeutic aid available to the doctors and hospitals in communities that need it. It should be stated here that the project is applicable only in communities with adequate hospital and laboratory facilities as well as competent medical direction.

The development of a successful volunteer blood donor project requires careful consideration of many factors relating to management. Paramount among these is the protection of the donor. The patient's interests are of course also important, but these are too self evident to need discussion here; but not so with the donors. When donors are invited to enroll for the specific purpose of giving blood without a fee they must be assured not only of the harmlessness of this procedure but also of a minimum of inconvenience and physical discomfort. It must be remembered that they enlist primarily for humanitarian reasons. They are glad to give blood when needed, provided they have reason to believe it will be put to good use and that their contributions are appreciated alike by doctors, hospital officials and others with whom they come in contact. Unless they are treated courteously from the time they are called to report at the hospital until they return, and unless the technic of taking blood is simple and skilfully performed, they will not continue their names on the rolls. We have learned through experience that to maintain a satisfactory list of donors it is necessary to give them every consideration to which they are entitled.

It is therefore important that certain regulations be instituted within the hospital, governing the handling of donors and standardization of the technical phases of transfusion. These regulations must provide for uniform procedures and technics. The donor should be courteously received when reporting to the hospital. Transfusions should be performed by the indirect or citrate method. Incision of the vein must not be permitted. The caliber of the needle used should not exceed 14 or 12 gage. The donor should be in a recumbent position during venipuncture and in a suitable room not occupied by patients. One or more resident physicians or surgeons thoroughly familiar with transfusion procedures should be assigned to this service. The donor should receive prompt attention and the arm should be properly dressed. He should be dismissed in good condition with an expression of appreciation by the attending physician or nurse. He should be fully satisfied if possible with the treatment accorded him. These are some of the fundamentals necessary for maintaining a successful volunteer donor project. They do not have the same significance when dealing with paid donors.

Then too the chapter must keep in constant touch with the donors by personal visits, letters or telephone calls, must iron out all misunderstandings and complaints and must keep them in a reasonably well satisfied frame of mind. Much detail work is necessary to maintain constantly a satisfactory list of donors and an efficiently functioning service.

Regulations governing the physical examination of donors, grouping and blood tests, equipment, methods and technics to be adopted are all important. These are a responsibility of the physicians and hospitals and must be carefully planned and supervised. It is also necessary to establish some regulation governing the selection of indigent and semi-indigent patients so that the use of volunteer donors will not be abused.

It is the responsibility of the chapter to organize the project, to maintain an adequate list of donors, to transport them to the hospital, to safeguard their interests and to maintain a properly functioning organization day and night. It is the responsibility of the hospitals and

3. Oliver, P. L.: The British Red Cross Blood Transfusion Service, *Guy's Hosp. Gaz.*, March 16, 1935.  
4. Report of the British Red Cross Society for the Year 1937, Blood Transfusion Service, p. 26.

physicians to work out the technical phases of transfusion and to assist the chapters in maintaining high standards of efficiency. Thus far we have experienced little difficulty in enlisting donors and keeping them on the rolls.

Donors are recruited largely from among salaried workers and wage earners. They are usually the stable and respected citizens of the community and constitute a very desirable group both from a health point of view and from willingness to serve. They should preferably be between the ages of 18 and 40, in robust health, free from syphilis and other communicable diseases, and have a readily accessible vein in the arm. A hemoglobin content of 85 per cent and a normal differential blood count with no evidence of blood dyscrasias are required; also a negative Wassermann or other test for syphilis. They should be reexamined every six months or oftener if practicable. A Kahn or similar test and final cross matching with the patient's blood are required at the time of transfusion.

The Baltimore chapter has recently inaugurated a most carefully planned project. It differs from donor services in other chapters in that the entire program is conducted under the direction of a physician employed by the chapter. The donors are all examined and the blood grouped by him and an associate who is especially qualified in hematology. Such a plan should insure an efficient service, although it is applicable only in larger cities. In smaller chapters the project is conducted by the chapter executive and staff of assistants under the direct supervision of a special committee. The chairman of this committee is invariably one of the leading physicians of the community. Here the physical examinations and the laboratory tests are performed on a volunteer basis.

The question is frequently asked as to what relation this donor project has to the development of the so-called blood bank, as originated at the Cook County Hospital, Chicago.<sup>5</sup> The latter is a procedure developed for collecting and storing blood under proper refrigeration until needed for transfusion. Up to the present time Red Cross donors have not been used for filling blood banks. They have been provided only for immediate transfusion purposes. It is possible, however, that in time the project may be modified, particularly for the larger hospitals.

The "blood bank" plan appears to be applicable for the present at least only in larger hospitals where transfusions are a daily occurrence. Since blood cannot be kept for an indefinite period, it might have to be discarded too frequently in hospitals where transfusions are given only occasionally. Wasting blood, particularly when given by volunteers, cannot be permitted. Then too we are not certain that donors would be willing to volunteer so readily if their blood is not to be used immediately. The blood bank may rob the project of some of its humanitarian aspects and thus interfere with the enrolment. Time and experience will determine whether our present project can be modified that way.

The success of the project depends largely on maintaining a constant list of satisfied and willing donors. Anything that may tend to interfere with that should

be carefully studied before it is used. Constant contact with the donors, adding new names to the list from time to time, cautious procedures within the hospital and courteous treatment are all essential. Physicians who use the service must recognize this and do everything possible to help protect the interest of the donor as well as the patient.<sup>6</sup>

## Clinical Notes, Suggestions and New Instruments

### PERIPHERAL NEURITIS DUE TO SULFANILAMIDE

A. M. ORNSTEEN, M.D., AND WILLIAM FURST, M.D.  
PHILADELPHIA

Current literature records the following reactions to sulfanilamide: agranulocytosis,<sup>1</sup> acute hemolytic anemia,<sup>2</sup> cyanosis,<sup>3</sup> purpuric and scarlatiniform eruptions,<sup>4</sup> exfoliative dermatitis,<sup>5</sup> toxic dermatosis,<sup>6</sup> photosensitization of the skin,<sup>7</sup> fever,<sup>8</sup> sulfhemoglobinemia,<sup>9</sup> methemoglobinemia,<sup>9</sup> optic neuritis,<sup>10</sup> precipitation of a psychosis<sup>11</sup> and the inhibitory action on spermatogenesis.<sup>12</sup> The following report is offered as a probable case of intoxication from the therapeutic use of sulfanilamide:

#### REPORT OF CASE

J. D., a Negro steel construction worker aged 42, was admitted to the neurologic service of Dr. A. M. Ornsteen at the Philadelphia General Hospital Feb. 11, 1938, because of weakness in the hips and legs since January 1. The past medical history was essentially irrelevant. A recently remarried widower, he had one healthy son by his first wife. He stated that he did not use alcohol in any form. With the exception of gonorrhea in June 1936, for which he was adequately treated, he had been well until reinfectd from extramarital exposure in September 1937. At a local hospital he was given 100.5 grain (0.3 Gm.) tablets of sulfanilamide and was told to take three every three hours. His prescription was renewed three times, so that from October 11 to November 15 he took 400 tablets (130 Gm.).

Although the urethral discharge soon ceased, pain and swelling developed in the joints of the legs and arms, and the right eye became inflamed. He was admitted to the genito-urinary ward of the Philadelphia General Hospital November 27. Smear and culture of material from the eye yielded no gonococci. Diagnostic impressions were resolving gonorrheal urethritis, gonorrheal arthritis, nonspecific conjunctivitis and balanoposthitis. He was given approximately four hours of fever therapy

of between 106 and 107 F. in the Kettering hypertherm, after which he felt so much improved that he signed his release from the hospital December 2. He felt well and gained weight until Jan. 1, 1938, when he noticed that his hips and legs were growing increasingly weaker on walking but a short distance, necessitating his sitting down and resting every few steps. His gait finally became so cumbersome that he had to use a cane for assistance. He stated that he felt no pain in the limbs but did note patchy numbness and paresthesias in the distal portions of the lower extremities, more marked on the left. This continued to the date of admission, although it was much improved. The systemic review was essentially negative, with the exception of the yellowness of the eyes during ingestion of the tablets.

The patient was well built and muscular. He was 6 feet 1 inch (185 cm.) in height, without lymphadenopathy; the skeleton was normal. There was no evidence of cyanosis or icterus. Fading maculopapular, erythematous, nonindurated lesions about 0.5 cm. in diameter were situated on the back, in the suprasternal region and above the pubes. The eyes, ears, nose, teeth, tongue and throat were normal with the exception of hypertrophied cryptic tonsils from which no pus could be expressed. There was no tenderness of the nasal sinuses. Examination of the heart and lungs showed that they were entirely normal. The abdominal organs were not palpable. The prostate was enlarged, soft and boggy. The upper extremities were normal. There was no difference in length, size or shape of the lower extremities; abduction of the thighs was markedly weakened. Other muscular movements were good. Moderate compression of the calves and hamstrings elicited sharp pains, more marked on the left. Flexion and extension of the legs on the thighs were well performed, but there was weakness on dorsiflexion of the left foot against slight resistance. Mental examination was negative. Neurologic examination showed a negative Romberg sign and normal cerebellar function. His waddling gait suggested progressive muscular dystrophy; muscular weakness about the pelvic girdle, however, seemed entirely responsible for the disturbed gait, as there was no difficulty in flexion or extension of the back. The cranial nerves were normal. There were no fibrillations. The abdominals, left cremasteric and achilles tendon reflexes were absent. Knee jerks were elicited only slightly on reinforcement. The Babinski sign was not present. All sensory modalities were normal, with the exception of diminution of pinpoint sensitivity below the middle third of the legs.

Examination of the blood revealed red blood cells 4,300,000, hemoglobin content 85 per cent, white blood cells 6,600, polymorphonuclear leukocytes 54 per cent, lymphocytes 42 per cent, monocytes 2 per cent. The Kahn and Wassermann reactions were negative. Examination of the spinal fluid was essentially negative. The blood sugar was 84 mg. per hundred cubic centimeters, the urea nitrogen 12 mg. Sulfanilamide was not detected in the blood. Prostatic smear and culture yielded no specific organisms.

The patient gradually improved on bed rest, mild sedation and brewers' yeast. Muscle tenderness subsided and the knee jerks were elicited without reinforcement at the end of two weeks. The achilles tendon reflexes, however, were still absent. Sensory signs had completely disappeared but motor weakness was still evident, although so much improved that the patient became ambulatory the entire day without the use of a cane. Before further studies could be completed the patient again signed his release from the hospital, February 28, believing that he was almost cured.

#### COMMENT

Bliss and Long<sup>13</sup> have demonstrated that large doses of sulfanilamide administered to mice produced symptoms of bilateral vestibular dysfunction and a curious spastic paralysis. Hageman<sup>14</sup> obtained similar results in his experiments. Custer and his associates<sup>15</sup> have demonstrated the toxicity of the drug to

the central and peripheral nervous systems of dogs, producing ataxia, spastic paralysis, loss of reflexes and blindness. Hankins<sup>16</sup> has produced nervous symptoms resembling somewhat decerebrate rigidity in rabbits and cats with large doses of the drug. Bucy<sup>17</sup> has reported optic neuritis in man.

Marshall, Emerson and Cutting<sup>17</sup> believed that the occurrence and intensity of the toxic effects in man from sulfanilamide depended on the susceptibility of the patient to the drug, the dose per unit of body weight and the efficiency of the kidneys in excreting the drug. Unfortunately, our patient left the hospital before the renal function could be determined.

The possibility of gonorrhea as the etiologic agent in this case was considered, but in the past ten years there have been only two cases of gonorrheal neuritis reported in the literature, both in foreign journals.<sup>18</sup> It is probable, then, that sulfanilamide was responsible for the neuritic condition in this patient.

#### CONCLUSION

Toxic neuritis with a progressive muscular dystrophy-like picture probably resulted from excessive ingestion of sulfanilamide (2,000 grains [130 Gm.] in thirty-five days).

Philadelphia General Hospital.

#### HEMOPHILIA TREATED BY VENESECTION

GEORGE B. LAWSON, M.D., ROANOKE, VA.  
AND  
A. B. GRAYBEAL, M.D., MARION, VA.

J. E. M., a white man aged 51, was admitted to the Jefferson Hospital in March 1931, acutely ill with hemophilia. He presented signs and symptoms pointing to the presence of hemorrhage in the meninges, pleural cavities and abdominal viscera. There was bleeding from the genito-urinary tract, and there were also many large areas of subcutaneous hemorrhages.

After several days the patient was worse and in what seemed a hopeless condition; feeling that possibly these hemorrhagic crises were an effort of nature for relief, my associates and I tried venesection. The results were surprising. Though the patient had been in a comatose condition, forty-eight hours after the venesection he was clear mentally and seemed in good shape physically. Since that time, a period of seven years, he has been constantly under the care of one of us (A. B. G.) and has had venesection done, with the removal of about 500 cc. of blood, every six or eight weeks. With the onset of fullness in the head and pains in the joints he voluntarily comes in for venesection, and the relief of symptoms is almost always immediate. Since 1931, moreover, he has been free from subcutaneous hemorrhage.

Until about 1923 the patient had had frequent spontaneous bleedings from the nose and the roof of the mouth, with relief from the marked symptoms in the joints. From 1923 until he first entered the Jefferson Hospital in 1931, however, he had had no bleeding from the nose or mouth, and the symptoms in the joints were marked; he was confined in bed at times as long as six weeks. Frequently too he had had subcutaneous hemorrhages without apparent trauma. Of especial interest was the onset of these; at some point he would feel a slight stinging pain, and the next day a large area of discoloration would appear.

In October 1937 the patient was again admitted to the Jefferson Hospital for study. The frequent venesections since 1931 apparently had had no detrimental effects; for he seemed in good condition. But he had been suffering, he reported, a slight discomfort in one knee for some years.

When he was examined at this time his heart was normal, with a blood pressure of 150 systolic, 90 diastolic. There was only

moderate peripheral arteriosclerosis. The electrocardiogram showed no essential abnormality. The hemoglobin content was 72 per cent (10.27 Gm.), the red blood cells numbered 4,130,000, the white blood cells 5,650: neutrophils 53 per cent, small lymphocytes 26 per cent, large lymphocytes 16 per cent, transitionals 2 per cent, eosinophils 5 per cent. The platelet count was 290,000, the clotting time, when a small test tube was used, was two hours and ten minutes, and the bleeding time forty-five seconds. The basal metabolic rate was plus 4. The clotting time, it seemed probable, had increased as the patient had grown older. Since his last visit to the hospital smaller amounts of blood have been removed because the hemoglobin content has been rather low. It is possible that the removal of smaller quantities is as beneficial as that of larger quantities.

During the patient's stay in the hospital in 1937 we had a woman with thrombopenic purpura who had been moribund. Transfusions had given her only temporary relief. Her blood and that of J. E. M. matched. With the hope of supplying some deficient element, we transfused 500 cc. of citrated blood into this woman's veins from the hemophiliac patient, but the response was about the same as what we had had with normal blood.

In studying J. E. M.'s history more carefully it was found that in 1929 he came to his physician (A. B. G.) and, because of the relief obtained by his previous severe spontaneous bleeding, demanded to be bled. This was at first refused but after insistence venesection was done with relief. This was repeated several times later. But we (Lawson, Jackson and Gardner) were not aware of this fact.

The family history of the patient is also most interesting. In addition to the uncles and brothers who were hemophiliac, he has one nephew aged 10 years (a sister's child) who has had bleeding from early childhood. When one of us (G. B. L.) saw him at the age of 3 he had a clotting time of two hours. Since then he has had many hemorrhagic crises, including an appendix operation (by Dr. J. C. Motley) in which much hemorrhage was found in the surrounding tissues. Dr. Graybeal, who was present at and advised this operation, is of the opinion that all the patient's symptoms were due to the hemorrhage. March 3, 1938, the boy was again seen by A. B. G. in an acutely grave condition. He had bleeding in the palmar surface of both forearms. His wrists were considerably swollen and could not be moved without intense pain. His fingers and entire hands showed extravasation of blood. There was a large hematoma on the left leg near the hip joint, with evidence of bleeding in the joint. There was also a large hematoma on the right leg around the hip joint with evidence of similar bleeding. So sore was the boy that he found it very painful to be moved in bed. His temperature was 102.6 F., pulse rate 126, white blood cell count 17,600; 275 cc. of blood was removed. In forty-eight hours the temperature, pulse rate and white blood cell count were normal, and the boy was sitting up in bed and did not complain of pain when any of his joints were moved. The clotting time of the blood was two hours and five minutes. Since that time the child has shown no evidence of recurrence of the bleeding and is now back in school and is leading a normal life.

Another patient (I. M. P.), a boy aged 15 years, and without a family history of bleeding, was sent to the Jefferson Hospital Jan. 19, 1938, by Dr. George Kolmer. Four days previously the boy had bitten his tongue slightly. Thereafter he began to complain of fullness in the mouth and tongue, though there was no evidence of sore throat. This fullness had increased with marked salivation but with very little soreness.

At the age of 2½ years he had marked spontaneous swelling in his joints, beginning in the right ankle. Since then this had continued at times, involving many joints. When he was 5 he suffered a minor laceration on the chin which, because of persistent bleeding, required hospitalization. At 7 years he had a retrobulbar hemorrhage causing the loss of vision in the left eye. When he was 12 a hordeolum of the left lid ruptured spontaneously, with bleeding so persistent that hospitalization was again necessary. In 1932 when one of us (G. B. L.) saw the boy he had a clotting time of thirty-seven minutes; two years later the clotting time was thirty-eight minutes.

Two weeks before I. M. P. was admitted to the hospital in January he had fallen from a pony and fractured his right fibula. There was marked swelling about the fracture. On examination the boy looked pale, except for his ears, which were pink. His mouth was partly open and his swollen tongue was visible. He opened his mouth with difficulty, the entire cavity being almost filled with the red swollen tongue. Under the tip was a gray slough. The floor of the mouth was markedly edematous, the edema extending to the right submaxillary angle and somewhat down into the right side of the neck. There was no light sense or pupillary reflex in the left eye. The lungs were normal. At the aortic area there was a slight systolic blow; the blood pressure was 120 systolic, 80 diastolic. The spleen was not palpable. The blood showed a hemoglobin content of 67 per cent (8.8 Gm.). The red cells numbered 2,700,000 and the white cells 9,900, with 70 per cent polymorphonuclear leukocytes. There were 346,000 platelets, and the clotting time was three hours and ten minutes. Venesection was done with the removal of 170 cc. of blood. The symptoms were markedly improved in twenty-four hours and the patient was soon able to leave the hospital. Two days after the venesection the clotting time was two hours and ten minutes.

#### COMMENT

In these venesections we have always used an aspirating needle in one of the veins of the arm, and there has been no subsequent bleeding at the point of insertion.

Our studies suggest that in hemophilia there are other factors in the hemorrhagic condition besides the delayed coagulation time, such as an increased volume of blood or more fragile capillaries, and it is possible that extravasation in the tissues may tend to increase hemorrhage.

On each of the three patients studied here venesection as a therapeutic measure has been used at the time of a hemophiliac crisis. It has also been used for a number of years on one of these patients at the onset of symptoms. In every case the results have been remarkably good when the hemorrhage has been in the tissues, either with or without trauma. Whether it would be of value in cases in which there is a lacerated wound, such as occurs after a tooth is pulled or a finger is mashed, we are not yet ready to say.

30½ Franklin Road.

#### GASTRO-ENTEROSTOMY CLAMP

CHARLES W. MAYO, M.D., ROCHESTER, MINN.

The accompanying illustration of a modification of the older gastro-enterostomy clamp is more or less self explanatory. The purpose of the shelf is simply to hold the bulging stomach away

Gastro-enterostomy clamp.

from the line of suturing, thus aiding in the actual performance of the gastro-enterostomy. For his aid in the design credit goes to Mr. Richard Grounds, who always has been cooperative in matters of this kind.

From the Division of Surgery, the Mayo Clinic.

## Special Clinical Article

### ECZEMA AND ITS PRACTICAL MANAGEMENT

CLINICAL LECTURE AT SAN FRANCISCO SESSION

FRED WISE, M.D.

AND

JACK WOLF, M.D.

NEW YORK

The name eczema has for many years been applied to a heterogeneous group of inflammatory dermatoses. The vexed question as to what to include and what to omit from the broad concept of eczema is discussed in hundreds of articles, of which many are repetitive and many unproductive. In the curriculum of one of the postgraduate courses in dermatology the lecture on eczema deals with "eczema venenatum, seborrheicum, hemostaticum, infectious eczematoid dermatitis, neurodermatitis, dermatophytosis and dermatophytids." This classification, while recognizing different entities, adheres to the morphologic classification of widely differing dermatoses.

In recent years much has been added to our knowledge of the subject. Numerous useful and carefully organized facts have come to light and lines have been more sharply drawn. Unna long ago removed seborrheic eczema, better termed seborrheic dermatitis, from the general group and established it as a specific entity bearing no relationship to other members of the group. The eruptions caused by infection with fungi, such as eczematous ringworm of the hands and feet and the old eczema marginatum of Hebra, are now also eliminated and classified etiologically. Moreover, clinical investigations and studies in allergy have segregated infantile eczema and the neurodermites.

Eczema is not a disease entity. It is a reaction form which can be produced by contact of the superficial portion of the epidermis with a great many substances, some of which are primary irritants, and also by physical agents. Clinically eczema is characterized by erythema and vesiculation, at times by the formation of papules, and in the subacute and chronic stages by scaling, thickening and lichenification. The eruption is almost always accompanied by itching. Histologically eczema is characterized by spongiosis, vesiculation, acanthosis and parakeratosis of the epidermis and by edema, vascular dilatation and cellular infiltration, primarily perivascular, of the cutis.

The term eczema is restricted by some authorities to eruptions known or proved to be from hypersensitivity to contacts. While such limitation narrows considerably the number of dermatoses which can rightfully be called eczema, a great number still remain which fit into the eczema group morphologically but in which neither hypersensitivity to, nor contact with, any injurious agent can be proved. It has been suggested that the term eczematoid dermatitis may be used as a kind of "blanket indictment" to designate these various obscure members of the group, and—one might add—to cloak our ignorance respecting the fundamental causes of certain eruptions of the eczema family. This would add nothing to our understanding of the problem, since, as has often been pointed out, it would be illogical

to call an eruption eczema when the responsible agent is known and by another name when the etiologic agent has not been clearly determined or remains unknown.

#### PATHOGENESIS AND TESTING

A proper understanding of the pathogenesis of eczema is impossible without consideration of certain immunobiologic phenomena. The substances which provoke eczema in the sensitive person are often harmless to the normal person. The list of eczematogenous substances runs into the thousands, and with each new dye, each new chemical reagent and each new chemical substance introduced in industry another substance is added to the long list. R. L. Mayer has classified these substances under the following headings: (1) artificial manures, (2) cleaning materials, (3) oils, solvents and varnishes, (4) acids and alkalis, (5) aromatic oils, (6) alkaloids, (7) drugs of various composition, (8) soaps, (9) shoe creams and dyes, (10) paints and dyes, (11) disinfectants and (12) inorganic salts.

Many of these substances are primary irritants and, according to the duration of the contact, will produce erythematous, vesicular or necrotic reactions when applied to any skin. Others, for example certain mercury compounds, will produce eczematous eruptions in the normal person only if the concentration of the active agent is sufficiently high. In testing to demonstrate hypersensitivity it is therefore necessary to apply the allergen in a concentration which will not produce a reaction in the normal person but which will yet be sufficiently high to produce a reaction in the hypersensitive person. This optimum concentration has been worked out for a great many substances. For any new and suspected agent the concentration of the substance to be tested must be carefully determined.

#### TECHNIC OF TESTING

The eczematogenous (or suspected) substance is applied to a small area of normal skin, preferably on the forearm in adults and the back in infants; it is then covered with a piece of impermeable tissue, such as oiled silk or cellophane, which is somewhat larger than the area, and this is secured in place by adhesive plaster. (For persons sensitive to adhesive plaster frisket and similar substitutes are used.) When the substance to be tested is in liquid form it is applied by saturating blotting paper or a small square of linen with the solution. Many substances can be used in their natural state by moistening a small fragment of the material, such as shoe leather or clothing. The test substance is usually left in place for from twenty-four to forty-eight hours. If itching or smarting is present before that time the substance should be removed; these subjective sensations are indicative of a reaction and there is no added advantage in permitting further cutaneous irritation. Positive reactions range from mild erythema to the formation of bullae and even necrosis. Most common is the small vesicular or the small papular or follicular eruption, which is in essence only a limited reproduction of the eczematous process as it occurs naturally.

The outcome of the patch test is by no means always an exact reproduction of the eczematous process as it occurs on the patient's skin. This is especially true in industry. The patch test is only a temporary contact with a concentration which may be totally different from that with which the patient is employed; the test is applied to an area of normal skin which may or may not be hypersensitive and which has not previously been subjected to contact. Furthermore, such important factors as moisture, whether due to immersion of the hands or to perspiration, and injury to the skin caused by friction or heat and cold or in the form of cuts, burns or bruises, all of which favor the develop-

ment of sensitization, are not taken into account. The positivity or negativity of a reaction must therefore be critically evaluated. Whereas the positive reaction obtained with an eczematogenous agent with which the patient is employed usually leaves little room for doubt, the negative reaction alone is not a criterion for the exoneration of the allergen.

In industry, where one is dealing with known eczematogenous substances and where more than one person in factory or plant is usually affected, the offending agent is often easily determined. Outside of industry success in identifying the eczematogenous substance is not always a simple matter, and much depends on the patient's memory and intelligence as well as the physician's diligence. Frequently the time, the patience and the ingenuity of the physician will be taxed. Even after exhaustive search the cause may remain obscure until repeated contact leaves no doubt. There will be a large number of cases in which the cause cannot be determined and the condition is clinically eczema. Of these more will be said later.

Tests performed with a group of eczematogenous substances on eczematous patients are positive ten times as frequently as similar tests on noneczematous persons. The positive reactions obtained in the "normal" subjects may indicate that these persons are potentially eczematous and may acquire eczema after adequate clinical exposure. While sensitization may be monovalent, eczematous persons are usually polyvalently hypersensitive.

#### ALLERGIC ASPECTS

In eczema one is dealing with a condition which fits in with Pirquet's concept of allergy. The shock organ involved in this allergic reaction is primarily the epidermis, with the possibility that the upper part of the cutis also takes part in the reaction. The allergen may reach the epidermis by direct contact, as is most often the case, or via the circulation, by injection, by ingestion or by inhalation.

Is eczema in all instances based on allergy? An affirmative answer would require the assumption that the vesicular eruption produced by physical agents or primary irritants is not eczema; that the eruption caused by a 0.1 per cent mercury bichloride ointment in the hypersensitive person differs in its form from the eruption produced by a 50 per cent mercury bichloride ointment in the normal person. Such an assumption is neither warranted nor necessary. Eczema, as a specific reaction form, bears comparison with urticaria, another reaction form, also produced by numerous agents. Lewis has shown that urticaria resulting from an antigen-antibody reaction does not differ from urticaria caused by physical agents.<sup>1</sup>

There is no unanimity of opinion regarding the existence of antibodies in persons with eczema of hypersensitivity. Attempts at passive transfer by the Prausnitz-Küstner method, according to our experience, always give negative results. There are isolated reports, to be sure, of positive results of passive transfer tests. Some of these results were probably due to an associated urticarial hypersensitivity; others were obtained in patients with flexural neurodermatitis, a dermatosis which may simulate eczema clinically and with which circulating antibodies can frequently be

demonstrated. If antibodies exist at all in patients with eczema, they may be cell fixed, attached to the epidermis, and, if they are, one would hardly expect to be able to demonstrate them with a technic such as the Prausnitz-Küstner test. The Königstein-Urbach method of passive transfer, in which blister fluid is used instead of blood serum and antigen is applied by contact or by injection, was devised to demonstrate cell-fixed antibodies. Even with this method, passive transfer of sensitivity is not altogether successful. More information is needed on the subject of antibodies and eczema.

#### MECHANISM OF SENSITIZATION

The mechanism of sensitization is unknown. Eczema may make itself manifest after what is assumed to be a first contact, after exposure for a relatively short period (even a few minutes), after a few weeks of contact or only after years of contact, continued or intermittent. The reasons for the development of the sensitized state and the variation in the time between exposure to an eczematogenous substance and the development of the sensitized state (the refractory period) are unknown. Once developed, the sensitized state usually persists. It may, however, manifest itself only as a temporary phase, disappearing completely or recurring after repeated exposure. In some instances continued exposure creates a desensitized state which persists only as long as the person remains exposed to contact with the eczematogenous substance and disappears after temporary removal from the source of contact.

A high percentage of the workers employed in Japanese lacquer factories are victims of severe eczema. Continued exposure to the lacquer at first aggravates the eruption and then frequently produces a state of desensitization in which the worker is able to continue without fear of recurrence. Cessation from work may, however, be associated with a loss of this desensitization, with recurrence of the eruption on further exposure. Here, in one industry, is an example illustrating the various states of latency, incubation of sensitization, desensitization and loss of desensitization.

#### AUTOSENSITIZATION

The duration of the eruption following a single contact with an eczematogenous agent is relatively short. According to the severity of the eruption and the efficacy of treatment, the skin will return to normal in from seven to thirty days. Occasionally the eruption becomes more extensive, even generalized, and remains for a somewhat longer period but then goes on to complete healing. It may persist for a long time, even many years, new lesions appearing at previously unaffected sites while older lesions are undergoing healing. To explain the persistence of this eczematous process long after all contact with the original cause has ceased, the concept of autosensitization has been offered. The patient becomes sensitized to some product of his own damaged cells (an autogenous antigen). This concept is a most helpful one and offers a working basis for the explanation of many perplexing problems.

Concrete evidence in support of autosensitization are the reports of cases in which serum from eczematous patches in trickling over normal skin has produced linear areas of eczema confined to the site of contact. Contact with this serum did not produce eczema in normal persons. Absorption of this serum into the blood stream may produce eczema on other parts of the body. Whitfield attributed the widespread eczema

1. Macleod and Muende have suggested the possibility of the existence of an X substance in the epidermis, the release of which brings about the eczematous reaction. This hypothetical X substance evidently bears the same relationship to eczema that the H substance of Lewis bears to urticaria and serves to explain the occurrence of eczema, irrespective of the source, whether chemical or physical, allergic or nonallergic.

following irritation of a localized patch of eczema and the universal erythroderma and exfoliative dermatitis of psoriasis, and other noneczematous dermatoses following the vigorous application of topical remedies, to sensitization of the patient to his own tissue products.

#### MUTATION (?) OF CONTACT ECZEMA

We investigated a group of cases among which were cases of chronic generalized eczema and universal erythroderma. Some of the eruptions simulated dermatitis exfoliativa, pityriasis rubra of Hebra, mycosis fungoides, suspected Hodgkin's disease and leukemia implicating the skin. The routine contact tests in such cases are almost invariably negative. Nevertheless, we discovered, after long bouts of "third degree" questioning, that a considerable proportion of these chronic intractable eruptions began in the form of ordinary eczema affecting at first mostly the hands and forearms and often following industrial or occupational activities. In such cases, instead of the expected improvement or cure after cessation of occupational contacts or as a result of rational treatment, a steady and relentless progression of the eruption takes place, eventuating in a form of generalized or universal erythroderma. Clinically and often histologically the eruption has lost all semblance to the alleged contact eczema which preceded it. In some cases it is erroneously diagnosed as mycosis fungoides.

#### PREDISPOSITION

Is there an inherited predisposition toward the development of eczema? The eczematous type of hypersensitivity has been experimentally produced in both animal and man. Low produced a hypersensitive state in normal adults to the primrose plant by friction with the leaves. Bloch succeeded in sensitizing 100 per cent of human beings with primin, the crystalline active principle of the primrose plant. Eczematous sensitization has also been produced with other substances, including simple chemicals, both by contact and by injection. Despite these results, one is not wholly warranted in discounting an inborn predisposition, since, as has been pointed out, the ease with which sensitization is produced experimentally is in itself a variable factor.

Eczema developing after what appears to be a first contact with a given allergen would seem to favor the existence of an inherited or inborn—in contrast to an acquired—hypersensitivity. Actually it is difficult to prove that previous contact with that substance or some related product did not take place. Theoretically the possibility of sensitization by way of the placental circulation must also be considered, although there is no evidence for this in the case of eczematogenous allergens. On the whole the evidence at hand seems to negate the existence of an inherited hypersensitivity, but with all the gaps in the physician's knowledge, especially with regard to that large group of cases in which no etiologic agent is discovered, the existence of a dispositional hereditary factor in eczema must remain *sub judice*.

Of the traditionally listed predisposing causes of eczema, such as alcoholism, digestive disturbances, malnutrition, mental and nervous debility, endocrine disorders and errors of metabolism, we can, with due humility, say that almost nothing is known. To date there is little proof to warrant the acceptance of these factors as of special significance.

On the other hand, it is certain that infections, bacterial and mycotic, may predispose to the develop-

ment of sensitivity to other substances. The exact manner in which the sensitization threshold is lowered is unknown. Dermatophytosis as well as the deep mycoses produces a hypersensitive state which can be demonstrated by the intradermal reaction to the injection of trichophytin. Trichophytin, however, also produces an eczematous reaction on patch testing, and, since eczematous sensitization tends to polyvalence, the eczematogenous property of fungous products may serve to broaden the base of sensitization to include other agents. Moreover, sensitization to external allergens is facilitated by injury of the skin, in this instance injury produced by infection. Bacterial infection as a possible prelude to sensitization finds its best illustration in those cases of arsphenamine dermatitis in which sensitization appears to be based on a focus of infection.

It has previously been pointed out that sensitization may be localized. An occasional factor which seems to control this localization is previous damage to tissue. This damage may be the result of nutritional disturbances, as with varicose eczema; of previous inflammation from infection, as with ringworm infection, or even of inflammation from exposure to sun and wind.

One is led to conclude that the term allergic eczema must refer to eczema based on allergy in contradistinction to eczema in which allergy does not play a part. Unfortunately some authors use the term to designate an entirely different dermatosis which is also called disseminate neurodermatitis, pruritus with lichenification, exudative eczematoid and atopic dermatitis. While the condition was formerly classified with the eczema group there is at the present time little justification for continuing the use of a name for a disease which differs clinically and histologically from eczema and which by the use of the qualifying term allergic adds to the confusion.

#### THE INFANTILE ECZEMA-NEURODERMATITIS COMPLEX

Atopic dermatitis, or neurodermatitis, is a distinct disease entity. It is primarily a disease of youth, manifesting itself early in life, usually from the second to the fifth year, but it may appear at any time in life. It is a disease subject to spontaneous remissions and recurrences and is more prevalent during the fall and winter months. In New York and its vicinity a surprising number of patients return with a recurrence at the end of September or early in October, but to date no significant reason for this time relationship has been ascertained. While atopic dermatitis is common during the first two decades of life the incidence thereafter is much smaller and the intervals between attacks are longer.

#### CLINICAL ASPECTS

Atopic dermatitis favors the neck and flexures and attacks the antecubital and popliteal areas, the wrists (most often the dorsolateral aspects) and the face, especially the eyelids, forehead and upper lip, but often appears on other areas as well. In the very severe variety, which is fortunately the less frequent, the eruption may be universal. Clinically neurodermatitis is characterized by dry, scaly, scratched, thickened, lichenified and hyperpigmented areas with outlying small papular satellite lesions. Vesiculation is uncommon and is usually the result of irritation, chemical or mechanical. The eruption is accompanied by severe and sometimes maddening pruritus. Atopic dermatitis

of the scalp, except as an extension from the neck to the suboccipital region, is unusual. A common observation, however, is the diffusely scattered small blood crusted lesion resulting from excoriations with the comb and finger nails. We have not noticed this form of eruption in association with other dermatoses. Whenever it is present we feel that it is important in a differential diagnosis. A not infrequent part of the clinical picture is the dry, scaly, fissured and crusted eruption involving the dorsal aspects of the fingers and to a lesser degree the hands. In the absence of other features of neurodermatitis the true nature of the eruption in these locations is apt to be overlooked. In infants and children a widespread keratosis follicularis of the trunk is common.

In the majority of cases a family history of asthma, hay fever, infantile eczema or atopic dermatitis is obtained. The personal history may include asthma or hay fever or, if the patient is unfortunate enough, both of these. In over 60 per cent of the cases, infantile eczema appears to be a prodromal manifestation of disseminate neurodermatitis of childhood, adolescence and adult years. Like patients with asthma or hay fever but unlike those with eczema, patients with neurodermatitis in the majority of cases give immediate wheal and flare reactions to foods and inhalants on scratch or intradermal testing. The sensitivity is usually polyvalent. In almost all instances circulating antibodies can be demonstrated by the Prausnitz-Küstner test.

Not all eruptions clinically diagnosed as atopic dermatitis are associated with positive reactions to scratch tests. The differences between those which are and those which are not associated with positive reactions are subjects for further study. To differentiate atopic dermatitis further from the eczema group of diseases, hypersensitivity, as determined by the patch test, is no greater in the patient with atopic dermatitis than in normal persons. Nosologically atopic dermatitis belongs with the asthma-hay fever complex.

#### INFANTILE ECZEMA

Included in the comprehensive term infantile eczema are many of the vesicular, scaly and crusted itching eruptions of infancy. Clinically and histologically infantile eczema fits in with the adult form of eczema. However, certain characteristics of infantile eczema serve to differentiate it sharply from the adult form. Among the most important of these are the following: 1. A frequent familial history of asthma, hay fever, atopic dermatitis or infantile eczema is obtained. 2. Asthma or hay fever is common in later years in the children affected. 3. Wheal and flare reactions to tests with foods and inhalants are frequent. The unexplained reaction to egg white is especially common, its frequency according to some statistical data ranging as high as 90 per cent. Unfortunately the elimination of the substances to which positive reactions are obtained does not often bring about a cure of the eruption. 4. As the patient grows older the eczema has a pronounced tendency to disappear for a time, either wholly or partly, to be followed after varying periods by a morphologically and clinically different form of eruption, namely the disseminate form of neurodermatitis (atopic dermatitis).

Transition forms in which the clinical manifestations of neurodermatitis are present before healing of the eczema has taken place are not uncommon. The point to be stressed is that one is here concerned with

the early and late manifestations of one and the same dermatosis—the infantile eczema-neurodermatitis complex.

Not all forms of infantile eczema fall into the category of atopic dermatitis. Some are not based on atopy but are the result of irritation of young and tender skin caused by such substances as soap and wool or irritation due to an insufficient change of napkins. As compared with older children and adults, infants are not often subjected to contact with eczematogenous substances, and contact eczema is correspondingly uncommon. Seborrheic dermatitis of the scalp and face is, on the other hand, relatively common and if left untreated may go on to the development of a vesicular, crusted and impetiginized eruption sometimes clinically indistinguishable from the atopic form. Combinations of atopic and seborrheic forms seem to be common in infants.

#### TREATMENT

It is obvious from what has already been said about the multitudinous exciting or precipitating causes of eczema that scientific treatment must rest on the elimination of the cause. When that is possible there will in most cases be a spontaneous *restitutio ad integrum*. Symptomatic treatment is, however, essential in all cases, whether or not the cause has been determined, to secure relief of itching and burning and to hasten a return of the skin to normal. Even when the eczema is of undetermined origin, symptomatic treatment alone is sufficient to effect a cure in almost all cases, but the tendency to recurrence is relatively greater.

#### GENERAL TREATMENT

The patient with widespread or generalized eczema is a sick person. He needs rest in bed, the application of topical remedies by a competent nurse or orderly, the judicious administration of sedatives and the adjustment of splints or restraining devices to prevent scratching. He may require treatment by injections of various drugs or by roentgen therapy. Such treatment cannot be carried out when the patient is ambulatory and only with difficulty when he is confined to his home. He should be hospitalized to enable one to carry out procedures such as patch tests and various clinical and laboratory investigations. Hospitalization has the added advantage of removing him from his previous sources of contact, a measure which is sometimes helpful in determining the cause of contact eczema, especially when there are complications and the cause is obscure. Moreover, hospitalization considerably reduces the duration of illness and disability in the majority of cases.

The successful treatment of eczema is dependent on the relief of its most distressing symptom, pruritus. Pain in comparison is pleasurable, and it is this sensation which the patient substitutes in an orgy of scratching to relieve a crisis of itching. The cycle is a wicked one, for scratching aggravates the eczematous process, which in turn causes more pruritus. Listed hereafter, together with the various antieczematous remedies, are some of the more useful antipruritic drugs. It is necessary to call attention to the fact that drugs such as ethyl aminobenzoate, which relieve pruritus by their effect on the terminal nerve endings, are rather frequent sensitizers. Their effects must be closely watched. We are in the habit of performing patch tests and determining the patient's reaction to these substances before permitting him to use the prescribed remedy.

If necessary—and if the pruritus is at all pronounced it is necessary—rest and relief of itching must be

attained by the administration of sedatives. Bromides, barbiturates and salicylates will have to be tried. Opium and its derivatives are never to be used, no matter how severe the pruritus.

Paroxysms of itching may be so severe as to be uncontrollable by any known means, the patient scratching himself until his skin is lacerated and bleeding. On the other hand, itching may be slight and may often be readily controlled by topical applications. A properly adjusted, well padded splint on the upper extremities or a restraining jacket to prevent scratching and rubbing often proves to be a great aid in the control of subjective symptoms. At times even the lower extremities require splints. Once the patient has learned the value of restraining devices, he will actually demand their application during the night.

In general, baths, even baths medicated with starch, bran, oatmeal, potassium permanganate or tar, are

TABLE 1.—Remedies Used in Treatment of Eczema

*For Acute Eruptions*

Zinc oxide: zinc oxide ointment (U. S. P.); shake lotion; zinc-oil mixture  
Boric acid: boric acid ointment (U. S. P.); 3 per cent aqueous solution  
Solution of aluminum acetate (N. F.), or Burow's solution, diluted 1 to 10; Burow's paste  
Salicylic acid, 2 per cent solution; 2 to 4 per cent shake lotion or paste  
Resorcinol, 2 to 4 per cent solution  
Tannic acid, 2 to 5 per cent solution; 3 per cent shake lotion  
Silver nitrate, 0.125 to 0.25 per cent solution

*For Subacute Eruptions*

Ichthammol, 5 to 10 per cent shake lotion and ointment  
Solution of coal tar (N. F.), 5 to 10 per cent shake lotion and ointment  
Naftalan,\* 5 to 20 per cent ointment  
Crude coal tar, 0.5 to 4 per cent ointment  
Ammoniated mercury, 2 to 10 per cent ointment

*For Chronic Eruptions*

Oil of cade, 5 to 15 per cent ointment  
Oil of birch tar, 5 to 15 per cent ointment  
Crude coal tar, 5 to 20 per cent ointment; may also be painted on full strength  
Resorcinol, 4 to 10 per cent ointment  
Salicylic acid, 4 to 10 per cent ointment  
Sulfur, 4 to 10 per cent ointment  
Ammoniated mercury, 4 to 10 per cent ointment  
Chrysarobin, 0.5 to 10 per cent ointment

*Antipruritic Remedies*

Menthol, 0.25 to 1 per cent  
Phenol, 1 to 2 per cent  
Ethyl aminobenzoate, 3 to 10 per cent  
Solution of coal tar (N. F.), 3 to 15 per cent  
Ichthammol, 3 to 10 per cent  
Salicylic acid, 1 to 2 per cent  
Sulfur, 2 to 4 per cent  
Chloral hydrate, 2 to 4 per cent  
Spirit of camphor, 1 to 4 per cent

\* A distillate from Caucasian shale.

inadvisable in the case of acute and subacute eczema. We have time and again seen an existing eruption well on its way toward healing exacerbate after a single bath. On the other hand, in the case of dry, chronic, infiltrated eczema, medicated baths are of proved value and add much to the patient's comfort.

Except in the cases of eczema in which some specific food or foods is assumed to be at fault, diet plays a rather small part in the treatment. There are indications of the usefulness of dietetic restrictions in some cases, to be sure, and the future may hold much in store for patients who exhibit some error of metabolism, but at present the question of diet in the treatment of eczema is in a rather sad and chaotic state. Perutz, Gerson and others advise a low protein, high carbohydrate, moderately high fat regimen, with fruit juices and vegetables. When the condition is obstinate a salt-free diet deserves a trial.

While the literature is replete with reports of excellent results achieved with the intravenous administration of the various calcium salts; sodium thiosulfate, and strontium bromide in dextrose solution, our own experience with these drugs has been for the most part disappointing. Other nonspecific measures, such as the administration of the patient's own blood (autohemotherapy) and injections of turpentine and various forms of milk, have sometimes appeared to be effective, but it is difficult to judge the results since they were obtained in cases in which other forms of treatment were used in conjunction with these nonspecific measures.

Hyperpyrexia is another nonspecific measure which at times proves effective in the treatment of the widespread, generalized recurrent eruptions with a changing clinical picture in which one finds lesions of a different character, varying from the active exudative to the chronic lichenified type, in different stages of the disease. At one time the eruption takes on the appearance of universal erythroderma and at another it is indistinguishable from mycosis fungoides. For the production of heat various measures have been used, including cabinet baths (infra-red), diathermy (radiotherm) and typhoid vaccine. Recurrences of this type of eczema are nevertheless common.

Arsenic continues to hold an important position in the therapy of chronic eczema. It should never be used during the acute phase. In the subacute stage it is to be administered only if the eruption proves refractory to other therapeutic procedures. We prescribe solution of potassium arsenite in gradually ascending doses, starting with 3 minims (0.2 cc.) twice daily after meals and increasing the dose by 1 minim (0.6 cc.) daily until 20 minims (1.2 cc.) is taken. The dose can be maintained at this high level for several weeks. A course of arsenical treatment usually lasts from four to six weeks. Arsenical medication must not be frequently repeated, and the danger of delayed late effects, pigmentation, keratoses and epithelioma, must ever be kept in mind. At the first signs of intolerance, which include sweating of the palms, a coated tongue, dryness of the throat, abdominal pain and puffiness of the eyelids, the administration of arsenic should be discontinued. For subcutaneous administration sodium arsenate 2 Gm., phenol 2 Gm. and distilled water sufficient to make 100 cc. is used. This formula is also administered in gradually ascending doses starting with 3 minims once daily and increasing by 1 minim daily until a dose of from 20 to 25 minims (1.2 to 1.5 cc.) is reached, at which level it is maintained for a short time.

LOCAL TREATMENT

Thus far we have purposely refrained from any lengthy discussion of the morphologic characteristics of the various stages of eczema. They are too well known to bear repetition. In a discussion of the treatment, however, a consideration of the morphologic characteristics is of great importance, for the treatment is directly dependent on the clinical characteristics of the eruption. It is not a matter of indifference whether a salve, a lotion or a wet dressing is used in a given case. Each has its indications.

In table 1 are listed the most common remedies used in the treatment of eczema; as indicated, the remedies range from weak ones used for the acute eruptions to strong ones used for the chronic eruptions.

The number of remedies has purposely been limited. As in other branches of medicine, the intelligent and judicious use of a few well chosen remedies is wholly preferable to the haphazard use of many. To enhance

the effect of a lotion or salve a combination of two or more active ingredients is often preferable to an increase in the concentration of one active component.

If the choice of a remedy is important, the method of application is not less so. It does not suffice to prescribe a salve or a lotion and instruct the patient to "go home and use it." Remedies must be properly

applied. Success in the hands of one physician and failure in the hands of another often depend on this factor alone. The patient should be instructed minutely in every detail; he should be advised (if this is indicated) to massage the salve into the affected area for several minutes by the clock, to apply a liberal layer, to cleanse the area with olive oil before each application and if possible to bandage the affected part. Wet dressings must be kept wet lest they serve as a source of irritation on becoming dry. Lotions are to be applied often and liberally, so that they thoroughly cover the affected area. Once daily the caked and crusted lotion should be removed by sopping the part with a 3 per cent aqueous solution of boric acid or with olive oil.

In the acute erythematous and vesicular stage, wet dressings are the treatment of choice. They are cooling, soothing and antipruritic, allow for drainage of serum, relieve swelling and give the patient more comfort than any other single remedy. Solution of boric acid 3 per cent, solution of aluminum acetate (N. F.) diluted 1 to 10, resorcinol 2 to 4 per cent, tannic acid 2 to 5 per cent, salicylic acid 2 per cent, are all effective and satisfactory. For impetiginized eczema, resorcinol 2 to 4 per cent, or 1:2,000 solution of mercury bichloride should be used for their bactericidal powers. Silver nitrate in a 1/8 to 1/4 per cent dilution is not sufficiently popular as a wet dressing. Were it not for the staining qualities which preclude its use on exposed portions of the body, silver nitrate would be the wet dressing of choice; it is to be highly recommended but must be employed with caution because of the possible development of argyrosis. Wet dressings should be bandaged whenever practicable and should be kept wet continuously until the dry, scaly stage is reached.

While lotions and pastes are not as effective as wet dressings during the acute stage, they are nevertheless satisfactory and in addition offer the patient a simpler and therefore often a more desirable form of treatment. They are prescribed when a wet dressing is not advisable.

The lotions and pastes listed in table 2 are recommended.

In the dry desquamative stage, treatment with a bland ointment such as boric acid (U. S. P.), zinc oxide ointment (U. S. P.) or Lassar's paste until the skin returns to normal, is indicated. Burow's paste, cooling, soothing and softening, may be helpful in the acute or in the dry desquamative stage.

The subacute stage, with its dry, crusted, scaly areas, is best treated with lotions or salves. We are rather partial to lotions, particularly for widespread eruptions. They offer a cleaner and more satisfactory form of treatment to the patient, are more easily applied and do not require bandaging. In subacute eczema the pathologic process is superficial enough to be influenced by the active ingredients in the lotions. The following substances are recommended: solution of coal tar (N. F.) 5 to 10 per cent, ichthammol 5 to 10 per cent, resorcinol 4 per cent, salicylic acid 2 to 5 per cent and tannic acid 3 per cent. These are to be added singly or in combination to the calamine lotion described. Burow's lotion may be used as a base instead of the calamine lotion for all the active ingredients except tannic acid. Tannic acid is incompatible and causes the mixture to cake. Ethyl aminobenzoate 5 to 10 per cent and menthol 1/8 to 1/4 per cent or other members of the antipruritic group should be added whenever necessary to control the pruritus.

The various active ingredients listed for subacute eruptions may be used in ointment form as in table 3.

Superficial, unfiltered roentgen rays in fractional doses are a useful adjuvant in the treatment of subacute eczema.

It is the dry, chronic, thickened, lichenified, scratched eczema which offers the most difficult problem and taxes

the skill of the physician. The remedies employed are all reducing agents, and of these tar is outstanding. It is the most important and reliable single therapeutic agent used in the treatment of chronic eczema. Salicylic acid 3 to 10 per cent and resorcinol 4 to 10 per cent added to the preparation promote the effects of the tar by their keratolytic action.

Fractional doses of roentgen rays are most helpful in the treatment of chronic eczema in which the skin is

lichenified and thickened, especially when it is localized. Frequently the use of roentgen rays is the only satisfactory form of treatment and patches which have resisted topical remedies of all kinds will yield to four or five weekly exposures. In cases of recurrent eczema overdoses must be guarded against and roentgen therapy must be stopped when the limit of tolerance is reached.

Certain regional eczemas require special consideration. In the case of acute vesicular dermatitis of the extremities accompanied by swelling and tension, elevation of the extremity, upper or lower, by improving circulatory dynamics will hasten a return to normal.

TABLE 5.—Zinc-Gelatin Formula

Mixed zinc oxide and calamine.....	30.0
Gelatin .....	30.0-40.0
Glycerin .....	50.0
Water .....	ad 200.0

The course is otherwise often a protracted one. In the case of subacute and chronic eczemas of the extremities, especially the lower, the application of Unna's zinc-gelatin boot will bring relief to the patient and will promote quicker healing than any other measure we can recommend. We encase the extremity in a stockinet bandage, apply the warmed, liquid zinc-gelatin mixture directly to the stockinet and then bandage the extremity firmly with an ordinary gauze bandage. We find this method superior to the application of the zinc-gelatin mixture directly to the skin followed by cotton wadding or the tedious application of the mixture directly to the bandage in its endless circuitous course. Bandages already impregnated with a gelatinous material which dries readily and which form an excellent boot are now on the market.

There are various modifications of Unna's original zinc-gelatin formul , all satisfactory. Proprietary preparations are also available.

The application of the bandage may be preceded by the application to the lesions of tar ointment or gentian violet 2 per cent in 50 per cent alcohol. The gentian violet is useful in the treatment of the nummular, vesicular, crusting patches so often found on the extremities.

Ecze ma of the axillary, pubic and crural regions is best treated with shake lotions such as calamine lotion with the addition of antipruritics and active agents such as solution of coal tar (N. F.) 3 to 10 per cent and resorcinol 2 to 4 per cent. Salves in these areas lead to annoying folliculitis.

The eyelids must be treated gently. Wet dressings of boric acid solution or solution of aluminum acetate (N. F.) diluted 1 to 15 are usually helpful. The patient must be in a reclining position, and the wet dressings should be applied for several hours daily. In the acutely erythematous, edematous stage, continuous application of wet dressings for from twenty-four to seventy-two hours gives the greatest amount of relief and brings about the most improvement. In the dry, scaly stage, boric acid ointment or the 1 per cent yellow mercuric oxide ophthalmic ointment is satisfactory. Boric acid ointment should also be applied in the intervals between wet dressings. Roentgen rays in small fractional doses are sometimes necessary to control the process.

INFANTILE ECZEMA

The subject of infantile eczema forms too large a chapter for lengthy discussion in this communication. Only the more important measures will be indicated.

In the first place the infant is to be kept at rest with the extremities tied to the sides of the crib or splinted to prevent scratching and irritation. Errors in diet, such as overfeeding in the case of the obese child and insufficient feeding in the case of the poorly nourished child, must be corrected. Idiosyncrasy to milk or some other article of food in the infant's diet is often at fault. Elimination of the food product in question, boiling of the milk, addition of hydrochloric acid and substitution of a soybean preparation for milk are all helpful measures which can be tried. If possible the diet should be arranged by consultation with a pediatrician.

Locally, White's crude coal tar ointment<sup>2</sup> offers excellent results in the treatment of infantile eczema. The tar and zinc oxide are each separately mixed, as are the starch and petrolatum, and then these two combinations are thoroughly mixed. If a distilled crude coal tar product is used the folliculitis which commonly follows the use of ordinary crude coal tar will often be prevented. The salve should be thoroughly applied to the face and scalp and then covered with a mask. Not all eruptions require such diligent treatment. The remedy should be tempered to the clinical condition, and a mild infantile eczema will often yield to treatment with 10 per cent naftalan in zinc oxide ointment. The eruption on the body, if present, is not as infiltrated and requires milder remedies, such as 1 to 2 per cent of oil of birch tar in zinc oxide ointment, 5 per cent naftalan ointment or a shake lotion.

It might be well to repeat that the treatment of eczema in its various and diversified forms and aspects requires meticulous attention to detail on the part of the physician and whole hearted cooperation on the part of the patient.

TREATMENT OF ATOPIC DERMATITIS

The logical treatment of a constitutional disease such as the infantile eczema-atopic dermatitis complex should naturally be directed to the constitutional basis on which the disease depends. Unfortunately little can be done to influence the atopic state. The immunologic approach serves as a basis for comprehension but is of little practical therapeutic value. Neither the elimination of

the specific allergens to which the patient gives test reactions nor specific hyposensitization is frequently successful. There are isolated instances, to be sure, in which the elimination of food or environmental allergens appears to be beneficial, and it is the good results in these cases which warrant testing, elimination and hyposensitization; nevertheless these results are more exceptional than usual. From a practical point of view reliance has to be placed on topical remedies and symptomatic and general measures. These give the most satisfactory results.

2. Crude coal tar 2 Gm., pulverized zinc oxide 8 Gm., starch 8 Gm. and sufficient petrolatum to make 30 Gm.

In the general treatment of atopic dermatitis, mental and physical rest is essential. Almost invariably the person with neurodermatitis is highly strung, ambitious, alert, overactive and highly emotional. These characteristics are already evidenced in the precocious, restless infant, in constant motion during the entire consultation. Not infrequently the attack is precipitated by some unusual strain and in youngsters often occurs just prior to or during examination periods. Whatever the immediate cause, it is essential to regulate the patient's life, remove all sources of irritation and advise sufficient rest. This is not a simple matter, as any one who has had to deal with this problem will readily acknowledge. In one instance a sufficient amount of rest may mean retiring two hours earlier, in another enforced afternoon rest periods may be required and in still others hospitalization is necessary.

Rest is abetted by the administration of sedatives, and there need be no great hesitancy in adopting this measure unless there is a history of hypersensitiveness. Bromides and barbiturates (especially phenobarbital) are valuable. Intravenous bromotherapy (strontium bromide) is used, but its superior qualities are questionable. Sedation is a necessary part of the treatment and is used not only to lower the threshold of irritability but also to allay the uncontrollable pruritus from which the patient suffers. Treatment directed to the imbalance of the autonomic nervous system is not sufficient unto itself, but as part of a scheme in which other forms of treatment are used, atropine, pilocarpine and ephedrine find a place.

Without pruritus there would be no neurodermatitis, and local treatment is based on the one essential point of controlling pruritus. Lotions and ointments are equally valuable, but only trial and error can tell which is the more suitable for the individual patient. Ointments often seem to give more relief and more comfort. Their use can be combined, the more cleanly lotion being used in the daytime and the ointment at night. Usually the simpler the treatment the better it is. The preparations in table 6 are suggested.

The ointment can be fortified by the addition of ethyl aminobenzoate for its antipruritic action, and instead of naftalan other tar preparations such as carboneol<sup>3</sup> (3 to 6 per cent), oil of birch tar (5 to 10 per cent) and crude coal tar (5 per cent) may be substituted or added in combinations. As a rule these are satisfactory, and if they are not it is doubtful that any other topical remedies will be more beneficial. If the lesions have become impetiginized, from 3 to 5 per cent ammoniated mercury should be added to the ointment. Ointments must be gently massaged in for several minutes; a liberal layer must be left over the affected area, which is then properly bandaged. We have found bandages rather irritant and have used stockinets on the extremities with satisfaction. In cases of severe and extensive involvement proper treatment cannot be carried out without the help of trained personnel and hospitalization.

Bathing is not contraindicated. With a widespread eruption it is distinctly beneficial and sometimes gives more relief than any other single remedy. The warm colloid bath prepared with starch, bran or oatmeal is preferred; it should last for from twenty to thirty minutes but may be much more prolonged if beneficial.

Of the many other remedies used, arsenic and calcium, especially the former, are the most useful. The fact that neurodermatitis is a recurrent disease and that

courses of arsenic cannot be repeated indefinitely must not be lost sight of. Solution of potassium arsenite in the usual dose is administered by mouth unless gastric irritation necessitates a change to subcutaneous administration, when the 2 per cent solution of sodium arsenate is preferred.

Roentgen therapy is the most powerful antipruritic. As such it forms a most important part of the therapy of atopic dermatitis, but the problem of roentgen therapy is one with many facets and its use should be confined to the specialist.

200 West Fifty-Ninth Street.

## Special Article

### THE PHARMACOPEIA AND THE PHYSICIAN

#### THE TREATMENT OF INFANTILE ECZEMA

FROM THE POINT OF VIEW OF THE PEDIATRICIAN

LEWIS WEBB HILL, M.D.

BOSTON

*This is one of a series of articles written by eminent authorities for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopoeial Committee on Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—ED.*

In order to discuss treatment intelligently, it is first necessary to indicate briefly what is meant by "infantile eczema."

It would be not only futile but presumptuous for a pediatrician to attempt a definition of the word "eczema" when dermatologists have been trying for years to formulate one that would be satisfactory to every one and have not yet succeeded. Suffice it to say that there is in infancy a certain group of dermatoses which is perhaps best called the "eczematoid" group, and that the dermatoses included in it present certain morphologic and clinical characteristics which set them apart from other dermatoses. The component elements of the group are the seborrheic, the atopic, the contact and the mycotic forms of dermatitis.<sup>1</sup> Added to any one of these may be the elements of traumatic or chemical irritation or of pyogenic infection. Combined forms are frequent, and the morphology is so variable that it is often not possible to classify a given case accurately. The last two members of the group, contact and mycotic dermatitis, while they do occur in infancy, are not common and will not be discussed.

Most "eczemas" of infancy are of the seborrheic or atopic variety, and combinations of the two are common.

Seborrheic dermatitis occurs especially in fat babies during the early months of life. It is likely to begin with intertrigo of the folds and greasy scaling of the scalp ("cradle cap"). It may then extend to other parts of the body, most often the face, neck, shoulders and trunk. It is essentially a dry, scaly eruption and rarely oozes unless there has been rubbing. On the body the patches of dermatitis, usually with sharply

3. A product of crude coal tar dissolved in carbon tetrachloride.

This is the first of three articles on this subject.  
1. Sulzberger, M. B.: J. Michigan M. Soc. 34: 78 (Feb.) 1935.

defined margins, may be large or small, round or oval, often a yellowish pink and with a tendency to clear in the center. By fusion of several patches, large sheetlike areas are sometimes formed. The scales may be silvery white and dry, somewhat suggesting those of psoriasis, but more often they are yellowish and greasy. There is sometimes a tendency to erythroderma, typically seen in Leiner's disease (erythrodermia desquamativa), which is regarded as the most severe type of seborrheic dermatitis. Leiner's disease is uncommon in this country.

There is only moderate itching, or sometimes none, and in an uncomplicated case protein tests on the skin are negative. The etiology is not settled, and a discussion of the various theories of etiology would be out of place here. There is no evidence to indicate that seborrheic dermatitis is of allergic origin; and it is not associated with asthma or hay fever. Permanent recovery after a few weeks or months is the rule.

Atopic dermatitis is the most common form of "eczema" in infancy. By the word "atopy," suggested by Dr. Arthur Coca in 1922, is meant a special and particular form of allergy in which there is a disposition, often determined by heredity, to a pathologic sensitization with foreign protein or protein-like substances and manifested particularly by the development of dermatitis, asthma or hay fever.

Atopic dermatitis in the infant is the commonest early expression of atopy. The eruption usually begins on the cheeks and is often preceded by seborrheic manifestations on the scalp. It may be confined to the head but more commonly spreads to the arms, legs and trunk, or it may become generalized, so that it covers most of the surface of the skin. The clinical appearance is variable: erythema, macules, papules, vesicles, scales, crusts and even wheals may exist all together. Added to these may be pyogenic infection and excoriations caused by scratching. The most characteristic elementary lesion, if one can speak of an elementary lesion in a dermatosis with such a varied morphology, is a small exudative papule which often goes on to frank vesiculation. These exudative lesions may rupture or may have their tops removed by scratching, with resultant formation of a small crust, so that there is often a punctate appearance which some have thought is quite characteristic of atopic dermatitis. Since vesiculation is often a prominent feature, in contrast to seborrheic dermatitis, oozing is common. Sometimes there may be rather large, somewhat thickened, fairly sharply defined areas made up of many small papulovesicles. In general, sharp margins are not characteristic of the eruption of atopic dermatitis.

The itching is intense; there is no dermatitis that itches more. Protein tests on the skin are often positive, the blood may contain transferable antibodies (reagins) and there is usually an eosinophilia. Some infants recover entirely after the end of the first year. All too commonly, however, the condition persists, either continuously or with remissions and exacerbations, well into childhood or even into adult life, and asthma or hay fever may become associated with it.

#### RELATIONSHIP OF ATOPIC TO SEBORRHEIC DERMATITIS

Modern dermatology has been able to separate the "seborrheic eczema" of the adult, which Unna first described in 1887, from true eczema. The distinction is more difficult in infancy. There are many cleancut cases that can be accurately and unequivocally assigned

to one group or the other, but seborrheic manifestations so frequently in young infants precede the development of true atopic dermatitis before any allergy has apparently developed, and mixed forms are so common, that there is evidently some relationship between the two. What this relationship is is by no means clear, and it would not be desirable in a practical paper of this sort to embark on a theoretical discussion. It is likely, however, that in the mixed forms the cutaneous symptoms are not entirely dependent on the antigen-antibody reaction of atopy and that there are other unknown etiologic factors.

#### LOCAL TREATMENT

There have been innumerable preparations recommended, many of which accomplish but little. I shall mention only the few that I have found the most reliable.

1. *Seborrheic Dermatitis*.—The Scalp: Prescription 1 is typical of those found valuable on the scalp. This ointment is applied heavily and is well rubbed in each day for four days; the scalp is then covered with a

#### PRESCRIPTION 1.—Salicylic Acid Ointment

	Gm. or Oz.
Salicylic acid .....	2
Petrolatum .....	129

Mix and make into an ointment.

cheap cotton cap. On the fifth day it is shampooed with soap and water, and the loosened scales are scraped off with a fine comb. This course of treatment is repeated as often as necessary. Good results should be obtained. As a rule scalps are not very hard to deal with.

The Face: Treatment of the face is more difficult because it is continually exposed and it is never possible to avoid a certain amount of rubbing. In my experience, for treatment of the face a paste made from crude coal tar, originally suggested by Dr. Charles J. White is excellent (prescription 2).

#### PRESCRIPTION 2.—Coal Tar Paste for the Face

	Gm. or Oz.
Coal tar, N. F. ....	7.5
Zinc oxide .....	15.0
Starch .....	30.0
Petrolatum .....	120.0

Mix and make into an ointment.

This is applied as often as is necessary to keep the face covered. It should not be used if pyogenic infection is present. After the tar paste has been used for about a week there should be marked improvement, but it is well to keep on using it until the skin is somewhat wrinkled and drawn. At this stage it is discontinued, and an ointment composed of equal parts of compound ointment of resorcinol (N. F.) and cold cream (rose

#### PRESCRIPTION 3.—Coal Tar Ointment for the Body

	Gm. or Oz.
Coal tar, N. F. ....	7.5
Petrolatum .....	60.0
Wool fat .....	60.0

Mix and make into an ointment.

water ointment, U. S. P.) is applied. This is continued as long as there is any appreciable dermatitis present. When the cheeks have reached a stage at which they are perhaps a little too red, with a tendency to chapping, but with no severe dermatitis, cold cream (U. S. P.) is substituted for the compound ointment of resorcinol and is continued indefinitely. If in the beginning the dermatitis is mild, it may not be neces-

sary to use the paste of crude coal tar, and good results are often obtained with one of the proprietary ointments of white tar (Ultraine, Taralba, Supertah).

The Body: For large areas on the body, a somewhat different tar ointment, without the zinc oxide and starch, is used (prescription 3). The entire trunk should never be covered with tar ointment or paste, since tar may be toxic if absorbed in too great quantity.

**PRESCRIPTION 4.—Undiluted Crude Coal Tar**

Coal tar, N. F. .... 30 cc.

**PRESCRIPTION 5.—Plain Talc for Intertrigo**

Purified talc ..... 120 Gm.

An ointment is not so satisfactory if there are only a few coin-size patches. For these, crude coal tar undiluted is painted on once a day with a cotton swab (prescription 4).

Intertrigo: For the intertrigo that is so often present, a dry dusting powder is better than an ointment. None is better than plain talc (prescription 5).

2. *Atopic Dermatitis.*—The Scalp: The same treatment is recommended as for seborrheic dermatitis.

The Face: If only a moderate amount of oozing is present, tar paste may be applied at once and is followed by compound ointment of resorcinol the same as for seborrheic dermatitis. If there is much weeping, this must be controlled before any ointment or paste is applied. It is not desirable to use a lotion which contains much sediment; there is too much caking. Liquid applications that have the active medicament in solution are the best. I have found prescription 6, originally suggested by Dr. Schlotz of Los Angeles, very efficient.

**PRESCRIPTION 6.—Lotion for Atopic Dermatitis of the Face**

	Gm. or Cc.
Solution of lead subacetate .....	15
Solution of aluminum subacetate .....	15
Distilled water .....	enough to make 120

Mix and make into a lotion.

**PRESCRIPTION 7.—Lotion for Atopic Dermatitis of the Body**

	Gm. or Cc.
Liquefied phenol .....	4.0
Solution of coal tar .....	15.0
Calamine lotion .....	enough to make 120.0

Mix and make into a lotion.

A saturated aqueous solution of boric acid is also good and is best if there is any tendency to infection.

Either of these is sopped on every hour until the oozing is controlled, which usually takes about three

**PRESCRIPTION 8.—Boric Acid or Salicylic Acid**

	Gm. or Cc.
Boric acid ointment .....	120

**PRESCRIPTION 9.—For Pyogenic Infection**

	Gm. or Cc.
If Oozy	
Solution of potassium permanganate (1:2,000) .....	240
Mix and label Apply frequently	
or	
Solution of boric acid, N. F. ....	240
Mix and label Apply frequently	
If Not Oozy	
Ammoniated mercury ointment (5 per cent) .....	120

days. Tar paste is then applied. The same principles apply to oozing on any other part of the body.

The Arms and Legs: These are treated in the same way as the face, with the exception that they should be bandaged. One layer of ordinary bandage is not enough; it is well to apply an outer elastic bandage also.

The Body: If there is an eruption of small macules or papules all over the trunk, dry powdering with talc is probably better than the use of an ointment or a lotion. If there are irregular areas of grouped papules and vesicles, prescription 7 may be used.

Erythroderma: If there is diffuse redness with scaling all over the body (atopic erythroderma), as there may be in some of the worst cases, strong ointments or lotions should not be used. Although there is no local treatment that is very efficient for this symptom complex, it has seemed to me that frequent powdering with talc is as good as anything. If this is too drying and an ointment seems indicated, either prescription 1, 8 or 9 will do no harm and may do some good.

**CONTROL OF ITCHING**

I know of no local application that is really satisfactory to control itching: the itching is too widespread. Five grains (0.3 Gm.) of phenol added to an ounce of

**PRESCRIPTION 10.—Sedative to Control Itching**

	Gm. or Cc.
Phenobarbital .....	0.2
Lactose .....	1.3

Mix and make into twelve powders.

ointment or lotion is probably as good as anything, but if the baby sleeps poorly at night an internal sedative is better (prescription 10).

**DIETETIC TREATMENT**

Some eczematoid eruptions (mycotic and contact) have nothing to do with the diet. This should be remembered by pediatricians particularly, for they have perhaps been too ready to believe that any and all cutaneous eruptions in infancy are of dietetic origin. Dietetic therapy is, however, often of value in seborrheic and in atopic dermatitis.

1. *Seborrheic Dermatitis.*—Since there is no specific food sensitization in uncomplicated seborrheic dermatitis, there is no indication for the omission of any particular food. Many infants with seborrheic dermatitis and intertrigo are too fat, and moderate underfeeding often has a favorable effect. It has also been

**PRESCRIPTION 11.—Feeding Low in Fat and High in Protein**

2 per cent milk .....	26 ounces
Water .....	9 ounces
Karo corn syrup .....	2 tablespoonfuls
Powdered casein .....	4 level tablespoonfuls

found that they are likely to do best on a formula which is relatively low in fat and high in protein. Such a formula for a 4 months old infant is given in prescription 11. Other than this they should be fed as any baby is fed.

2. *Atopic Dermatitis.*—Just as innumerable preparations have been used in the local treatment of atopic dermatitis, so have many methods of diet been recommended, most of which have enjoyed a brief popularity and have then subsided. At the present time, dietetic treatment in accordance with the immunologic observations is accepted by most pediatricians; and, while by no means entirely satisfactory, is undoubtedly superior to any other that has ever been recommended.

The theory most widely held is that the eruption is produced by a histamine-like substance which is either newly elaborated or set free by the union of the antigen or antigens to which the individual is hypersensitive,

with specific antibodies that are fixed in the papillary layer of the cutis. (See the publications of Marion B. Sulzberger.) In accordance with this theory the commonly accepted immunologic treatment is to determine by means of the cutaneous tests, history and clinical trial the antigen or antigens to which the patient is hypersensitive and to withdraw these from the diet or environment. Hyposensitization, while it may be occasionally useful, does not hold the important place in atopic dermatitis that it does in hay fever. In infancy, the food allergens are by far the most important, although there may sometimes be sensitization to environmental allergens, and these must be taken into consideration.

THE CUTANEOUS TESTS

It is often not possible to make sure by inspection alone whether an eruption is of the atopic variety. It is therefore desirable to do cutaneous tests on all infants with eczematoid eruptions, no matter what the structure. While testing of the skin is not always reliable and has many pitfalls and disappointments, it has revealed more about the essential nature of atopic dermatitis than has anything else, and has offered the best indications for etiologic treatment that have yet been available.

Positive Scratch Reactions to Foods in 100 Atopic Infants Under 1 Year of Age, All of Whom Reacted to One or More Allergens

Egg white .....	86	Rice .....	2
Milk .....	26	Corn .....	2
Wheat .....	17	Spinach .....	2
Oat .....	8	Pea .....	2
Barley .....	6	Carrot .....	2
Beef .....	6	Orange .....	2
Potato .....	4	Codfish .....	1
Haddock .....	3	Chicken .....	1
Tomato .....	3		

Three methods of testing are employed:<sup>2</sup> (1) the scratch test, (2) the intracutaneous test and (3) indirect testing (passive transfer). With infants the scratch test is preferable as a routine, but if it is negative it should be followed by an intracutaneous test with certain of the more important allergens. Indirect testing is somewhat cumbersome and complicated for average use but it is the only method that can be employed when the entire surface of the skin is covered with dermatitis.

*Allergens with Which to Test.*—It is not necessary to test young infants with a large number of allergens; tests should be made with the few foods they are eating, plus egg white whether they are eating it or not and with a few of the more important environmental allergens to which they may have been exposed. A positive test does not indicate with certainty that the dermatitis is due to the allergen in question; it indicates a possible etiologic factor only. If the positive test, however, is consistent with the history, it should be considered of etiologic significance until proved otherwise. The reactions to the scratch test by 100 infants are given in the accompanying table.

*Egg White:* Most atopic infants react to egg white although most of them have never eaten it. The sensitization is probably of intra-uterine origin (Ratner). In spite of frequent positive reactions, egg is

of but little practical importance as a causative factor in the atopic dermatitis of young infants, since most of them have never eaten it, and those who have have had it removed from the diet as soon as the dermatitis started, usually without any benefit whatever. A positive reaction to egg is of some diagnostic importance, however, since it usually indicates that the infant is atopic.

*Milk:*<sup>3</sup> Sensitivity to the proteins of cow's milk is probably the most important single cause of atopic dermatitis in infancy. As the intracutaneous test with milk is often positive when the scratch test is negative, it should always be done after a negative scratch test. A positive scratch test almost always indicates clinical sensitivity; a positive intracutaneous test sometimes does. In the presence of sensitivity to milk, one of the three diets may be used: (1) evaporated cow's milk, (2) goat's milk, either fresh or evaporated, (3) entire withdrawal of milk, and the substitution of a milk-free food, of which there are several on the market.

In my experience, evaporated cow's milk is not often very efficacious but is the best form of milk if cow's milk is to be used at all. Goat's milk is very uncertain but may occasionally give brilliant results. Withdrawal of milk and the substitution of a milk-free food give more consistent results, and I have had by and large better results with this in atopic eczematous infants than with any other form of dietetic therapy. It does not always work, however, for sensitivity to milk is by no means always the cause of atopic dermatitis, although it is in infants the most common one. Furthermore, in "atopic erythroderma," in which there is diffuse redness of the entire body, a great deal of coarse scaling and a general glandular enlargement, a milk-free diet is not often successful in spite of the fact that most of these infants are sensitive to milk. Nor should the milk-free foods be used in undernourished infants or in those with a tendency to diarrhea, for they may not be well tolerated by such infants, and a diarrhea may arise which may be more serious than the original dermatitis.

*Cereals:* Sensitivity to cereals, especially wheat, is common but offers no great difficulty, as there are so many to choose from.

*Vegetables:* Sensitivity to vegetables, especially peas and spinach, occasionally occurs but is rarely the most important or primary cause of the dermatitis.

*Orange Juice:* Scratch tests with orange are rarely positive; the intracutaneous test is occasionally positive. Sometimes, in spite of negative tests, the mother is certain that after the infant takes orange juice there is increased itching or an exacerbation of the eruption. Ascorbic acid is easily substituted.

*Fish Oil:* This may occasionally be a cause of atopic dermatitis—there is no evidence to indicate that it is commonly so. It should not be omitted from the diet unless a cutaneous test with fish has been done and is positive.

While it is more accurate to be guided by the results of cutaneous tests in planning a diet, it is possible, by knowing what foods most frequently cause trouble in the majority of atopic infants, to construct a diet which will come fairly close to meeting the immunologic indications even if cutaneous tests are not done.

2. For the details of testing of the skin see any of the textbooks on allergy.  
3. For a more complete discussion of this important subject than is possible here, see Brennemann, Joseph: Practice of Pediatrics, Hagerstown, Md., W. F. Prior Company, Inc., 1938, chapter 43, vol. IV.

Such a diet is as follows:

Evaporated cow's milk or goat's milk for mild cases or for any infant whose nutrition is poor

A milk-free food for moderately severe or severe cases if the nutrition is good

Cornmeal or oatmeal

Carrots or string beans

Banana

Fish oil

Ascorbic acid

#### NONSPECIFIC REGULATION OF THE DIET

Any digestive disturbance may aggravate atopic dermatitis; if there is a tendency to loose stools, constipation or vomiting, this should be corrected. If the baby is too thin he should be made fatter; if he is too fat he should be made thinner. If he has been taking too large an amount of milk, which is often the case, this should be reduced, or if he has been getting milk from a Jersey or a Guernsey herd his milk supply should be changed to one that contains less fat. There is rarely any advantage in changing from one sugar to another.

*Importance of an Adequate Diet.*—No matter what the cutaneous tests show, no changes in diet should be made which might jeopardize the general health of the infant: the whole child is more important than his skin, and an adequate diet on which he can thrive must be supplied at all times.

#### ENVIRONMENTAL ALLERGENS

Many eczematous infants have specific cutaneous hypersensitivity to house dust and feathers. It is difficult to prove that this has anything to do with the eczema, but it is well to allow no atopic eczematous infant to sleep on a feather pillow and to keep his room as free from dust as possible. There may occasionally be sensitivity to other environmental allergens, such as silk and wool, but the environmental allergens as a group are by no means so important in infancy as they are in later life.

#### RESULTS OF TREATMENT

Results of treatment are best in uncomplicated seborrheic dermatitis and in contact dermatitis when the cause has been found and removed. With some cases of atopic dermatitis in which there is marked sensitivity to cow's milk, brilliant results are obtained by the withdrawal of milk from the diet or occasionally by the use of goat's milk. The same sometimes hold true for other foods. In others, results are only fair, in many they are definitely poor, especially when there is erythroderma and profuse scaling, for which the name "atopic erythroderma" has been suggested. In this condition, in spite of definite sensitivity to various allergens, removal of these may have no effect nor is local treatment of any real curative value.

I have seen nothing in the literature, including my own contributions, which leads me to believe that any one really understands infantile eczema or that there is now any method of treatment, dietetic or otherwise, that is consistently and entirely satisfactory. And yet there is cause for encouragement in that appreciable progress has been made, particularly in atopic dermatitis, which has its roots deep in some of the most complicated and least understood phenomena of immunobiology.

While skilled local treatment is often very helpful, one cannot speak of "curing" an atopic person unless

there is at hand some method of making him nonatopic. There is no way of doing this at present, and the removal of allergens, while often effective and the best method of treatment based on etiology now available, does not really strike at the root of the trouble; in a way it is a surrender to an abnormal situation rather than a direct attack on it. Until there is a better understanding of the essential nature of atopy, this direct attack cannot be made.

The contact and mycotic elements, which I have not even discussed, still further complicate the situation in infantile eczema, and, in addition to these, infants have eczema-like eruptions of entirely obscure etiology which cannot be classified. One calls them "dermatitis" and lets it go at that. The picture is, however, gradually assuming a more definite shape. What is necessary now is an assembly of methodically and accurately collected facts, particularly as regards classification and the results of immunologic treatment. There is no disease in which it is more difficult to evaluate treatment, and it is necessary to be very conservative in attributing improvement to any therapy. Hypothesis and theory are necessary in the study of infantile eczema, as they are in the investigation of all natural phenomena. The trouble is that often in the literature of infantile eczema there have been too few solid facts to justify some of the conclusions that have been drawn.

Infantile eczema is not the exclusive domain of the allergist, dermatologist or pediatrician; it belongs to all of them, and each has something to contribute. Each must, however, explore the fields of the others more than has been done in the past if the best results are to be attained.

### Council on Industrial Health

THE COUNCIL ON INDUSTRIAL HEALTH HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. C. M. PETERSON, M.D., Secretary.

#### NOMENCLATURE IN INDUSTRIAL HEALTH

The Council on Industrial Health has from its inception considered that one of the first problems to which it might profitably give attention is nomenclature in industrial health. A committee of the Council was appointed to study the problem from a broad point of view and to prepare the following preliminary statement:

The language of industrial health is at present incapable of full expression within the strict confines of scientific terminology. It has been greatly affected by the particular environment of the worker and his special social relationships. For the most part the usages and idioms of industrial health have derived from the authority of court decisions, legislation and administration practices, the pronouncements of industrial organizations and of medical and nonmedical technical committees, as well as from the publications in the field. Variation in source and derivation has resulted in wide confusion. The general medical profession, therefore, needs to have available an analysis of the common terms used in industrial medical practice and to arrive at a clear understanding and a common acceptance of their meaning.

Any investigation which has for its purpose the inauguration of an industrial hygiene program must obtain accurate morbidity and mortality statistics. Frequently such statistical information is unavailable or is reduced in value through lack of adherence to uniform terms. Dictionaries and encyclopedias have supplied some assistance in understanding industrial medical terminology but, on the whole, there is little to which the medical profession

can turn at the present time for standard definitions of terms used in industrial health. The Council on Industrial Health, therefore, proposes to publish a compendium in which the frequently used terms of industrial medical practice will be defined and explained. It will be necessary to include explanations of certain expressions in fields of activity closely associated with industrial medicine. It is proposed that each term listed be provided with a brief and authoritative explanation. The ambiguities and perplexities of contemporary language in the field of industrial health will, as far as possible, be avoided. The compendium will not be a dictionary of terms in the ordinary sense or provide encyclopedic information, nor will its activity in any way duplicate or conflict with the work of the American Medical Association's Standard Classified Nomenclature of Disease.

It is hoped this compendium will serve a useful purpose to the general medical profession, acceptable to it as a first step toward the introduction of some measure of uniformity in the confusing terminology of today.

## Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

HOWARD A. CARTER, Secretary.

### BARACH-THURSTON JUNIOR OXYGEN TENT ACCEPTABLE

Manufacturer: Oxygen Equipment Manufacturing Company, 247 East Fifty-Sixth Street, New York.

The Barach-Thurston Junior Oxygen Tent is a portable unit designed for oxygen therapy. Complete equipment includes the tent canopy and elevating device, air-conditioning cabinet, motor blower, Oxy-Ator, Linde R50 Reducing Valve with gages, and an oxygen analysis outfit. It may be purchased without the two last mentioned items. The weight of the complete unit is approximately 85 pounds. It is mounted on five ball-bearing casters and is finished in hard synthetic enamel. All metal parts are chrome plated.

Barach-Thurston Junior Oxygen Tent.

The tent canopy is raised over the bed by means of a gear and rack appliance. It is adjustable from 48 to 68 inches from the floor. The canopy covers approximately three fourths of the bed. It has windows of cellulose acetate placed within spring steel window frames to protect against breakage. There are separate openings with slide fasteners placed at the side of the tent to provide for convenient nursing attention.

One claim made for the unit is that it will provide a concentration of approximately 50 per cent oxygen and maintain it for a flow of between 8 and 10 liters per minute. Any standard regulator or the Linde R50 unit may be used. An Oxy-Ator is attached to the reducing valve. Soda-lime is not used. The Oxy-Ator acts as a mixing chamber for removing carbon dioxide and conserving oxygen, according to the firm.

An air conditioning cabinet permits maintenance of the tent temperature between 50 and 70 F., with a relative humidity of from 35 to 50 per cent. The ice chamber, which is lined with tinned copper, has an ice capacity of 55 pounds. A brass air duct is so arranged that the air and oxygen entering the ice chamber must circulate through the ice before entering the tent, thus cooling the gas mixture.

The motor blower unit is housed in the lower part of the cabinet and circulates air through the tent in the desired direction by means of an adjustable deflector. According to the firm the air is changed with sufficient frequency to assure no

greater rise than 1 per cent in the concentration of carbon dioxide in the tent air without the use of soda lime. Two air ducts, one an inlet and one an outlet, are permanently fixed to the cabinet and may be extended in height.

In order to substantiate the claims made for the unit, it was investigated clinically by a competent physician and reported to give satisfactory service.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Barach-Thurston Junior Oxygen Tent for inclusion in its list of accepted devices.

## Council on Pharmacy and Chemistry

### REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

PAUL NICHOLAS LEECH, Secretary.

### TRI-COSTIVIN NOT ACCEPTABLE FOR N. N. R.

A physician submitted a query to the Council office with regard to the advertising used by Professional Laboratories, Inc., for its product Tri-Costivin. The drug, which is claimed to contain the hormone cholecystokinin, is said to be suitable for oral administration. Cited in the bibliography supporting this statement is the article by Dr. A. C. Ivy on *Gastrointestinal Principles* which appeared in *THE JOURNAL* Aug. 17, 1935, and in the A. M. A. publication *Glandular Physiology and Therapy*. Inquiry was made of Dr. Ivy concerning the firm's use of this reference. His attention had previously been called by others to the advertising for Tri-Costivin and he had written to the firm under date of Oct. 15, 1937, in part, as follows:

"I note that you claim that Tri-Costivin contains the hormone cholecystokinin and that Tri-Costivin is taken orally. I desire to inform you that no evidence exists showing that cholecystokinin is active when given orally, and all evidence known to me is to the contrary. I, therefore, request that you withdraw from your future advertising any reference to my work on the subject of cholecystokinin. The reference to cholecystokinin is entirely misleading, and I consider it to be gross misrepresentation of the known facts."

In reply to Dr. Ivy a representative of the firm, Clifford A. Williams, vice president, pleaded that the actual statements as they appear in the advertising must of necessity be so condensed that there is little opportunity for qualifying statements. Continuing, the firm stated:

"However, in the basic literature on the product the following paragraph appears:

"The chief stimulus of gallbladder contraction thus far discovered is the hormone cholecystokinin (Ivy, p. 442). This hormone can be extracted from the mucosa of the upper part of the intestine of animals (Ivy). Although this hormone is considered effective only when administered intravenously (Ivy), some stimulating effect on the gallbladder seems to result from oral administration as well."

"The final clause of this paragraph is based upon our own clinical and laboratory tests, which obviously combined the use of the extract of duodenum gland with the other ingredients of Tri-Costivin in simultaneous action and indicate that so administered orally, does exert some stimulating effect on the gallbladder.

"We will, as you request, withdraw from our future advertising any reference to your work on the subject of cholecystokinin.

"We will go further, in order to clarify any confusion which might exist. We will insert in the small supply of the small folder to which you refer a slip sheet containing about the same text as is quoted above from the later literature. This same slip sheet will be inserted on the page in the already printed later literature containing a reference to your work in the bibliography.

"Then we will write each of the physicians who have shown any interest in the product, by requests for samples or additional literature, calling their attention to the fact that your work did not reveal any evidence of cholecystokinin activity when administered orally.

"Trusting that this will meet with your entire satisfaction, beg to remain,"

Through the kindness of Dr. Ivy, the preceding correspondence was made available to the Council.

In the firm's advertising it is claimed that:

"At last a rational therapy has been devised for that most frequent manifestation of gastrointestinal dysfunction—chronic constipation. The recognition that this disorder is due to a multiplicity of factors has led to the development of a product which directs treatment to the underlying causes rather than to superficial symptoms. In Tri-Costivin the physician has for the first time a product which contains all the substances most essential for the stimulation of normal gastrointestinal function [eureka!]."

The folder then goes on to describe the various constituents of this preparation. Vitamin B<sub>1</sub> and B<sub>2</sub> concentrates are attributed with "appetite stimulating powers" and "their ability to stimulate the gastric secretion of hydrochloric acid . . . for the maintenance of normal muscular tonus." "Another important ingredient" is said to be "lacto-banana concentrate" which is attributed with "aiding the elimination of putrefactive organisms." The product also contains "Trilactic (trade mark) combined with calcium lactate." Trilactic is described as a "polymolecular form of lactic acid" and is attributed with reaching "the lower portions of the intestine where it serves in changing the bacterial flora."

Under the heading "Important Hormones Included" the firm notes the presence of cholecysmon for promoting "fat digestion and assimilation," as well as "pure bile extract" and "cholecystokinin." The efficacy of Tri-Costivin according to the manufacturer is "due to the fact that it supplies, in scientific balance [sic] the eight essential factors indicated for the treatment of gastrointestinal dysfunction as evidenced by impaired digestion or assimilation, by autointoxication or chronic constipation." The firm states "It is a brilliantly rational product aimed simultaneously at many of the causes, rather than the symptoms of chronic constipation." Although the Council is not impressed by the various claims of this firm, the copywriter's selection of the verb "aimed" is admired. Its use in referring to a product containing eight different active ingredients recalls to mind the "shotgun prescription" typical of therapeutics a half century ago. Professional Laboratories, Inc., like those in the past who have prescribed such mixtures, fail to take into consideration that in any given case constipation may be due to any one or more of the factors which they discuss, as well as a great many others which they omit, and that it is desirable to determine which one of these factors is present in each given case before prescribing a remedy. It is possible then and only then to prescribe suitable therapy for that case.

If it could be granted that this is "a brilliantly rational product" it would have to be on the basis that the preparation is suitable for self medication. Obviously, in such case, it would not be necessary to know or determine the causes of chronic constipation in any given case, but simply to prescribe this remedy and hope that one of the "shot" will hit the mark. As already noted, the firm claims that its own evidence indicated that cholecystokinin is orally effective. Does its own evidence refer to the oral use of cholecystokinin or to the oral use of Tri-Costivin, which contains in addition cholecysmon and bile extracts? Just exactly what "Trilactic" and "lacto-banana concentrate" are is not clear.

It cannot be denied that such a mixture as this may prove useful in a certain number of cases of chronic constipation. It may also relieve symptoms in certain cases which sooner or later, and probably sooner, will require much more careful study than is needed to prescribe this scattered array of substances. Although the manufacturer may plead that the product is advertised only to the medical profession, the fact remains that the prescription of such a remedy as this requires little medical knowledge. The Council on Pharmacy and Chemistry has long ago decried all "shotgun prescriptions." In the opinion of the Council a pharmaceutical containing "eight active essentials" and claimed to be a "brilliantly rational product" is not worthy of further consideration on the basis of available scientific evidence.

The Council declared Tri-Costivin unacceptable for inclusion in New and Nonofficial Remedies because (a) it contains a multiplicity of active ingredients the combination of which is not warranted in scientific medicine, (b) it is promoted with unwarranted therapeutic claims based in part or indirectly on scientific evidence which has been modified to suit the case at hand, and (c) it is marketed under a name which naturally cannot give any indication of its eight ingredients.

## Council on Foods

### ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

### BENEDETTO OLIVE OIL

*Manufacturer.*—Supreme Olive Oil Corporation, San Fernando, Calif.

*Description.*—Pure olive oil obtained from California olives.

*Manufacture.*—Ripe olives are crushed and oil extracted from the skin, pulp and pits by cold pressing. Water, soluble sugars and solids are separated and the oil is neutralized with caustic soda, washed with warm water, bleached with activated carbon and activated earth and filtered. The filtered product is then deodorized by fractional distillation to eliminate foreign odors and flavors.

*Analysis* (submitted by manufacturer).—Moisture 0.05%, total solids 99.95%, ash none, fat (ether extract) 100.0%, crude fiber none, carbohydrates none, specific gravity 0.913, free fatty acids (as oleic) 0.14%, unsaponifiable matter 0.52%, saponification value (Koettstorfer) 194, iodine value (Wys) 85.2, smoke point 123.9 C., melting point (fatty acids) 26.2 C., cottonseed oil (Halphen test) negative, sesame oil (Baudouin test) negative, peanut oil (Renard test) negative. Tea seed oil negative. Refractive index at 40 C. 1.4621.

*Calories.*—9 per gram; 255.6 per ounce.

### MRS. PALEY'S BABY FOOD— STRAINED CARROTS

*Manufacturer.*—Paley-Sachs Food Company, Houston, Texas.

*Description.*—Canned, cooked sieved carrots slightly seasoned with salt.

*Manufacture.*—Fresh carrots are washed, scrubbed, cut into small pieces, pressure cooked with the skins on, sieved, filled into glass jars, vacuum sealed and heat processed.

*Analysis* (submitted by manufacturer).—Moisture 90.0%, total solids 10.0%, ash 0.8%, fat (ether extract) 0.2%, protein (N  $\times$  6.25) 1.0%, reducing sugars as dextrose 2.3%, sucrose 1.4%, crude fiber 0.8%, carbohydrates other than crude fiber (by difference) 7.2%, calcium (Ca) 0.055%, phosphorus (P) 0.033%, iron (Fe) 0.0009%.

*Calories.*—0.3 per gram; 9 per ounce.

### (1) EMPSON'S BRAND TOMATO JUICE (2) KUNER'S BRAND TOMATO JUICE

*Distributors.*—Subsidiaries of the manufacturer: (1) The Empson Packing Company, Brighton, Colo.; (2) The Kuner Pickle Company, Brighton, Colo.

*Manufacturer.*—Kuner-Empson Company, Brighton, Colo.

*Description.*—Canned tomato juice, slightly seasoned with salt.

*Manufacture.*—Vine-ripened tomatoes are washed, hand selected, cored and again washed. The tomatoes are heated and the juice is extracted and homogenized. A closed system is used. Salt (0.58 per cent) is added and cans are filled, sealed and heat processed.

*Analysis* (submitted by manufacturer).—Moisture 93.1, total solids 7.0%, ash 1.2%, sodium chloride 0.8%, fat (ether extract) 0.1%, protein (N  $\times$  6.25) 0.8%, crude fiber 0.2%, carbohydrates other than crude fiber (by difference) 4.2%, titratable acidity as citric acid 0.5%, ascorbic acid, determined by titration with 2-6 dichlorophenolindophenol, 0.16 mg. per gram.

*Calories.*—0.21 per gram; 6 per fluidounce.

*Vitamins.*—As determined by chemical titration by the dye method the tomato juice contains approximately 16 mg. of vitamin C or 320 international units per hundred grams; 95 per fluidounce.

# THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

## STRUCTURE OF PROTEINS

A fundamental problem of modern biologic science is the elucidation of the structure of proteins. An increasing number of biologically important substances have been demonstrated to be proteins.<sup>1</sup> Several enzymes have been isolated in crystalline form, and each of these has been found to be a protein. Several of the hormones are also now known to be proteins or protein derivatives. More recently has come the astounding demonstration that crystalline proteins of high molecular weight can be isolated from infected plant tissues and that these proteins have a physiologic activity identical with that attributed to an infectious virus.

The proteins resemble one another in that all proteins on hydrolysis yield the same amino acids, although proteins may vary widely with respect to the number of these fundamental units and the quantity of each which may be present in their molecules. Nevertheless the close resemblance among the products of complete hydrolysis of proteins makes even more difficult the explanation of specific physiologic activity on the basis of chemical composition. If the amino acid composition alone is responsible for the physiologic activity of proteins, why does one protein exhibit enzymatic activity, another serve as a hormone, and yet a third be apparently without any significant physiologic function?

As the chemical properties of the individual amino acids do not adequately account for the individuality of proteins, investigators have sought a solution of the problem in the mode of linkage of the amino acids to one another.<sup>2</sup> In addition, the fascinating problem of the configuration of the amino acids in space has been given consideration. This phase of protein structure has developed from a realization that the large molecular size of proteins must of necessity place some physical limitation on the theoretical possibility of the amino

acids existing joined to one another to constitute a long chain. Thus a folding or bending back of the protein chain on itself has been visualized, with the construction of cyclic structures to form definite patterns. If the definite sequence of these amino acids in the protein molecule can be established, and if the pattern of the arrangement of these amino acids in space can be constructed, the solution of the problem of protein structure approaches realization.

Through the efforts of Bergmann and his collaborators<sup>3</sup> at the Rockefeller Institute for Medical Research, the frequency of occurrence of the various amino acids in a number of proteins has been established. These investigations demonstrate, for the proteins studied, a definite periodicity existing for each amino acid in the peptide chain. That is, a given amino acid recurs at a regular interval in the molecule. In gelatin, for example, aminoacetic acid represents one third of all the amino acids, while proline represents one sixth and hydroxyproline one ninth. The frequency of occurrence of amino acids has also been determined for egg albumin, hemoglobin, fibrin, silk fibroin and other proteins. It is apparent that the existence of a simple arithmetical ratio among the numbers of molecules of amino acids is not fortuitous but must represent a regularity in the structure of the protein itself.

The establishment of the order in which the amino acids in a given protein may occur in the molecule leaves still unanswered the large problem of the manner in which these amino acid residues are arranged in space. That a definite pattern must exist seems evident from a variety of chemical and physiologic evidence. Experimental studies of the orientation of protein monolayers<sup>4</sup> is suggestive evidence for a definite pattern of protein structure. The x-ray studies of Astbury and his colleagues<sup>5</sup> also show clearly the existence of a framework or gridwork, particularly in the fibrous proteins like the keratins; more recently this has been demonstrated also for other proteins. Furthermore, biologic evidence of the type of enzyme specificity, immunity and the synthesis of specific tissue proteins suggests a definite pattern for protein structure.

A development of the concept that there must be a regularly repeated design for the manner in which the amino acids arrange themselves in space is the cyclol theory of protein structure proposed by Wrinch.<sup>6</sup> She suggested that proteins are made up of closed polypeptide chains consisting of amino acid residues. It is postulated that the hexagonal folding of polypeptide chains into cyclol units permits the construction of

molecules which might conceivably contain hundreds of amino acid residues in orderly arrangement and provides a characteristic pattern for the complex protein molecule. Although the cyclol theory appears to find strong substantiation from theoretical considerations and appears to offer an explanation of many facts in protein chemistry and physiology, there has been available little experimental work testing the validity of this theory of protein structure. Recently, however, Wrinch and Langmuir<sup>7</sup> have presented fundamental data supporting the cyclol theory of protein structure. Of added importance is the fact that this contribution is based on a study of the important protein hormone insulin. Utilizing available data on the x-ray crystal analysis of the insulin molecule, it has been demonstrated by means of mathematical analysis that these data support the polyhedral structure predicted for the insulin molecule on the basis of the cyclol theory. The fact that several suggested important features of the insulin molecule are confirmed also by the treatment given the x-ray data strengthens the validity of the cyclol hypothesis of protein structure and presents more clearly what appears at present to be the most logical of the many suggestions of protein patterns that have been put forward.

### ELIOT'S QUIZ

Many of the former pupils of Dr. Ellsworth Eliot Jr. will place their beloved mentor among the great and inspiring teachers of medicine. In a book called "Eliot's Quiz, 1889-1913," to which Dr. Eliot himself contributed an essay on extramural medical education, they have reflected medical teaching as it was in New York City fifty years ago. Attendance at medical clinics and lectures then was voluntary. Students could graduate at the end of three years without attending a single college exercise other than the final examination. Conferences and recitations were unknown. The student was a mere spectator at the clinics and only occasionally had opportunity at bedside clinics to listen to the physical signs of pulmonary and cardiac lesions. However, the competitive examinations for the highly prized hospital internships in New York hospitals were difficult. Recognizing the shortcomings of instruction methods in the medical colleges, some professors organized "quizzes," conducted often at night, for a limited number of students who paid a fee. Dr. Eliot conducted quizzes for twenty-four years, beginning in 1889. To his personality and methods of instruction many of his 476 pupils give the credit for arousing and inspiring them to success later in their chosen fields.

Six of his students came to be deans of medical schools, sixty-one to be full professors, twenty to be associate professors, thirty-one to be clinical professors

and 111 to be instructors in medical schools. From this group also came 104 visiting surgeons, 100 visiting physicians, 161 consultants and forty-four visiting specialists. Ten of this group became medical missionaries and ten became commissioned officers in the United States Public Health Service. During the World War, 178 of Dr. Eliot's quiz pupils served as officers of the army and nine as officers of the navy. Five of them have served in the medical corps of the United States regular army for many years. All members of Dr. Eliot's quiz, with eight exceptions, were graduates of the College of Physicians and Surgeons, New York. Although a college degree was not then generally required for admission to medical schools, 402 of the 476 men in the quiz had graduated from college before going to medical school.

In editing this tribute to his teacher, Dr. Howard Fox has included short biographic sketches of practically all the members of the quiz as probably the best way to show Dr. Eliot the results of his methods of teaching.

Dr. Eliot was large and towering physically and his personality awe inspiring. His great force of mind and body aroused his students to work. A former student writes: "He centered on me all the horrors of his sarcasm, his kindly wit, his stinging rebuke, his concise statement of fact, and his power to put the fear of God in any one who failed to properly prepare himself for those quizzes through which we went." On one occasion Dr. Eliot told a student that at the next session he would be required to name each and every articulating facet of the tarsal bones and their articulations. The student now writes with pride that he did not submit then nor has he at any time since submitted to any such memorizing test as this. Another writes of a "beautiful spring morning in May when I was seated in Dr. Eliot's quiz gazing out of the window. Suddenly I heard his great booming voice say 'Jackson, what are you doing?' I replied that 'I was wishing the hell that I was out of here enjoying God's beautiful sunshine out of doors.'"

At times, the quiz was conducted from 10 p. m. to midnight. Later classes rebelled at these hours and they were changed from 9 to 11 p. m. The quiz was held in the back room of the ground floor of the English basement house in which Dr. Eliot lived. Along three sides of this room were chairs and in the center was a desk piled high with medical journals. Williams writes: "Here sat the old man leaning back in his swivel chair with his feet on the desk. As a part of the evening's ritual he always smoked a cigar and sipped a glass of milk."

When the medical schools finally began to teach medicine, the extramural quizzes became unnecessary and one after another they disappeared. However, "The Quiz Medical Society" was formed in 1897 at a

7. Wrinch, Dorothy M., and Langmuir, I.: *J. Am. Chem. Soc.* **60**: 2247 (Sept.) 1938.

meeting in New York City. From time to time this society has given "The Old Man" loving cups, once thirty years ago when he was engaged to be married, later when he became a father and more recently when Dr. Eliot's days had numbered three score and ten. The tradition of medicine is replete with similar instances, reflecting a personal relationship between instructor and student almost peculiar to medical education. Such admirations are a part of the humanity which is an integral part of the medical soul. Will the highly standardized impersonal teaching associated with present trends in medical teaching be able to develop any substitute to compensate for the loss of these relationships? The question is fundamental to the whole future of medical care.

## Current Comment

### SULFANILAMIDE-PYRIDINE

The use of sulfanilamide in the treatment of pneumonia has not been sufficiently encouraging to warrant recommendation of this product to replace specific antiserum. While sulfanilamide has value, the results are not striking. The fact, however, that this chemotherapeutic agent does possess some value in infections due to pneumonia led to the investigations of derivatives of sulfanilamide with a view of obtaining one which might have a more definite chemotherapeutic effect. Early this year English workers announced that the pyridine derivative of sulfanilamide described as 2-(p-aminobenzenesulfonamide)-pyridine ( $\text{NH}_2\text{-C}_6\text{H}_4\text{SO}_2\text{-NHC}_5\text{H}_4\text{N}$ ), or sulfanilamide-pyridine, had been found to protect mice against pneumonia invasion to a much greater extent than was possible with sulfanilamide. The drug is patented and marketed in Great Britain by May & Baker under the nondescriptive name of M & B 693,<sup>1</sup> or "Dagenan." Merck & Co. Inc., the American firm which has obtained the patent rights for the product in this country, has, to its credit, not placed the product on the market; instead it has placed it in the hands of competent investigators in chemotherapy and pneumonia to determine more definitely its dosages, advantages and limitations. While published reports containing the details of the studies thus far are not available, THE JOURNAL has received communications from a few investigators, all of whom agree that the product has promise in the treatment of certain types of pneumonia. Fortunately the preliminary studies are being made before the product is widely distributed. With any new preparation, careful animal experimentation must be followed by cautious clinical trials to determine its pharmacologic effects. The substance has not yet been submitted to the Council on Pharmacy and Chemistry but the firm undoubtedly will submit

the product before it is actively promoted. The Council is also considering the choice of a name for the substance which may be used in scientific literature. Recently the press devoted much space to the development of this product. The demand for it might have yielded serious consequences except that the new food and drug law prevents its sale over the counter. Moreover, Merck & Co. is cooperating fully in determining both the usefulness and the hazards associated with the product before making it generally available.

### FIRST ANNUAL CONGRESS ON INDUSTRIAL HEALTH

One of the first activities of the Council on Industrial Health of the American Medical Association is the conference to which leading representatives of the groups interested in improving the physical and environmental status of the working people are being invited. The program appears on page 2128 of this issue of THE JOURNAL. The papers in this inaugural conference will review past accomplishments and appraise future needs. The discussions will be confined largely to the medical organization approach to industrial health problems in contrast to the purely clinical discussions which occur at many other meetings. In addition, sections of the program will, for purposes of orientation, outline the contributions and programs of governmental and independent organizations. Aside from its primary value of acquainting the profession with activities now going forward, it is thought that there will be the added advantage of reducing duplication of effort by agencies in industrial health. The sponsorship of a forum of this character by the American Medical Association amply indicates that the physician has a fundamental interest in seeing that medicine is properly represented in discussions involving health control of the employed population. Even more important, it is hoped that this meeting and the following meetings will represent in the eyes of the profession its own determination to find out what its best and most effective contribution should be toward improving the health of the individual worker.

### COMMERCIAL MISUSE OF INVESTIGATORS' NAMES

The report on Tri-Costivin in this issue of THE JOURNAL (p. 2118) calls attention to an embarrassment frequently suffered by reputable scientists through the misuse of their names in the commercial exploitation of pharmaceutical preparations. As in the instance reported, authors can usually obtain promise to delete their names and reference to their articles from such advertising copy once they object to the firm responsible for the infringement. The misapplication of purely scientific material in the promotion of new pharmaceutical preparations is unfortunate. This is especially apparent at a time when many leading manufacturers are spending huge sums to provide adequate facilities for research.

1. American physicians long ago gave up such unscientific methods of naming products as by letters or numbers. "Dagenan" is a name which in no way indicates the composition of the product, and its use is to be deprecated.

# ORGANIZATION SECTION

## FOR A FREE PROFESSION

Speaking as a member of the Committee on Economics of the Medical Society of the District of Columbia, Dr. Thomas E. Mattingly recently gave to the press a statement of his views of objectives of medical organization. The statement is so succinct and so well phrased that it would seem to deserve wide circulation. Dr. Mattingly, who incidentally appeared before the Grand Jury which is investigating organized medicine, said:

I am a member of the Medical Society of the District, and I believe in all the objectives of organized medicine.

We would like the people of Washington to be patient with us—to have faith in us and to believe that our social objectives are just as altruistic but infinitely less speculative than those who seek our indictment.

We believe that here on the weakest sector of human rights, a voteless community, we are using the only means we have to prevent our own destruction and degradation. Surely no one can expect us to initiate or be party to our own undoing.

Perhaps there has been an element of error in our method but men in desperation, fighting against odds—for what they regard as their very existence—are just as prone to forget the niceties of warfare as those who wage it.

Our objects are simple, and we believe self justified. No matter what method of medical practice is finally evolved, common sense tells us that it should embody all the safeguards and guaranties which made us cherish the old.

First and foremost is the unqualified right of the patients to choose their own doctor and determine the conditions under which he may continue to serve them.

The second, that no subsidy of taxpayers' money be given one group of citizens which is not available to every other citizen in the same circumstances.

Third, that the doctor be obliged to compete for his patient's favor and patronage and that his security be earned by merit and not apportioned by political favor.

Four, and this is in the nature of a conclusion, that under no plea of emergency should the patient be persuaded to delegate the control of medical practice to those who promise more than reason and experience tell us they can deliver. Whatever the faults of the present system of medical care, it has not

added to the heavy burden the taxpayer must bear in generations to come. It at least has the virtue of paying its way.

These are principles in equity and even if the old system must perish, these corner stones of our progress must, and should, remain.

Finally, we would like to call attention to the grave dangers, the terrifying potentialities, of allowing any agency of government other than the lawmaker to legislate through subterfuge, even if the end desired should seem to justify such a means. We hold that, if laws are old and antiquated and are not applicable to a modern need, it is the province of the legislator to change them.

It is not amiss to remind those thoughtless enthusiasts who have no scruple against unconstitutional and undemocratic short cuts to their political rendezvous with power that it was by this very mechanism that monopolies, in the sense of the anti-trust laws, came into being. By interpreting the "due process clause" of the fourteenth amendment to mean that it applied to corporate property as well as to the newly liberated slave, the corporate fiction was endowed with human rights. Instead of the lawmaker making a law to apply specifically to new social and economic conditions, it allowed the legalistic mind to interpret a law dealing with a human being who had ceased to be property as being applicable to property that had become a human being.

We hope that it is neither amiss nor presumptuous to ask every true liberal who believes in social progress, attained by equity and evolution rather than by fiat, to join us in our desperate stand to prevent a repetition of the grave errors of the past. Forgive us if we have offended. We will try with every resource at our command to earn your further favor.

## AMERICAN MEDICAL ASSOCIATION STUDY OF MEDICAL CARE

### Seven Nebraska Counties

Seven counties in Nebraska have returned their summary sheets in the Study of Need and Supply of Medical Care. These seven counties are Pawnee and Nemaha in the southwestern corner of the state, Nance, Howard and Franklin in the central and southern parts, and Sioux and Dawes in the northwestern corner of the state. These counties have an area of 4,861 square miles and a total population of 65,772 (U. S. Census 1930). Practically all the people are engaged in farming. There are only two counties which have incorporated cities with more than 2,500 inhabitants (Dawes with the city of Chadron, 4,606, and Nemaha with the city of Auburn, 3,068, U. S. Census 1930).

In the whole area there were only 237 people engaged in manufacturing in 1929. A negligible number were engaged in mining and forestry. Consequently, the income of the majority of the inhabitants in the seven counties is obtained from farming.

Nebraska, especially the western part, is in the area known as the Great Plains, where arid and semiarid years are so frequent that they create an exceptionally difficult agricultural hazard. In this area, conditions of distress due to climatic adversities are very evident and much of this land is submarginal for agriculture.

Two thirds of the years from 1910 to 1934 were arid or semiarid for the Northern Great Plains area.<sup>1</sup>

This report also includes a study on the income of the inhabitants of the Great Plains area in which it stated that 60 per cent of the income was derived from the production of wheat and other grains. The other 40 per cent is derived chiefly from stock ranches. The average annual net income from wheat production on a 640 acre farm in this area between 1912 and 1934 was \$1,007.97. This includes years of bumper crops and high prices. In twelve of those twenty-one years there was an actual net loss, including the years 1933 and 1934. In general, regardless of the use of the land in this area, periods of heavier than average rainfall and unpredictable droughts at irregular intervals are responsible for severe economic distress.

The report concludes that in most cases farmers in the semiarid area of the Great Plains cannot earn more than a meager living from the land. A livable income, it is believed, can be obtained only through government subsidy, which would be financially prohibitive for a long period of time.

1. Migration and Economic Opportunity. Report of the Study of Population Redistribution, Industrial Research Department, Wharton School of Finance and Commerce, University of Pennsylvania Press, 1936.

The following figures, taken from the Consumers Market Data Handbook, Department of Commerce 1936, will give some indication of the average net income and the number of persons on relief in Nebraska, and in the specified counties:

There was a total of 24,939 income tax returns for the state, 0.7 per cent of the total number of returns for the whole United States in 1933. There were 2,499 persons who reported incomes under \$1,000, 16,587 between \$1,000 and \$5,000, 4,023 between \$3,000 and \$5,000, 1,363 between \$5,000 and \$10,000, 436 between \$10,000 and \$40,000, and thirty-one reported an income of \$40,000 or over. It is evident that the majority of the people who filed income tax returns had a net income between \$1,000 and \$3,000, but only 1.8 per cent of the total population for the state made an income tax return, and only 0.7 per cent of the persons living in the seven counties had sufficient net income to necessitate filing income tax returns. These seven counties contain 4.7 per cent of the total population in the state.

From July 1934 to July 1935 the average number of persons on relief rolls in the state was 171,933, or 12.5 per cent of the total population, while the average number for these seven counties was 6,175, about 9.4

pharmacists made no report on the number of prescriptions compounded free, at cost or at reduced fees.

The county, with the aid of federal funds, provided medical care for the indigent. No private agencies provide care for the indigent. In determining a patient's ability to pay for medical services, the hospital and the welfare agency considers each case individually. During 1937 there were no cases of persons in need of medical care who were unable to obtain necessary services from either the hospital or the physician.

Seven of the eight physicians reported that they were performing preventive medical service, but it was estimated that only 10 per cent of the children who entered school for the first time in 1937 were successfully vaccinated against smallpox. A physician or a midwife was in attendance at all obstetric cases during 1937, and there were no known deaths from childbirth. The infant mortality rate was not given. The physicians are not receiving any kind of subsidy or guaranty to encourage them to remain in their community.

Persons and Organizations Which Provide or Arrange for Medical Services

County	Population	Physicians	Dentists	Pharmacists	Nurses	Medical Relief Agencies	Public Health Departments	Hospital Beds	No. of Miles the Nearest Physician Is from Any Person
Pawnee.....	9,423	9	5	13	1	1	1	126	10
Nemaha.....	12,356	12	8	13	1	1	1	123	6
Nance.....	8,718	6	5	5	3	1	1	13	20
Howard.....	10,020	7	5	7	3	1	1	5	15
Franklin.....	9,091	7	4	7	1	1	1	1	30
Sioux and Dawes....	16,160	11	8	8	2	2	2	35	30

per cent of the total inhabitants in these counties. The percentage of personal income tax returns and the percentage of persons on relief in these seven counties are low compared to the percentage of persons making income tax returns and the percentage of persons on relief in the state. However, since none of these counties have large cities in which there are more people making tax returns, and more persons on relief than in rural areas, these seven counties may be considered average rural counties in Nebraska.

Pawnee County

During 1937 the one hospital in Pawnee County reported 80 per cent occupancy in the private rooms and 75 per cent in the semiprivate rooms and wards. The daily hospital rates are \$3.50 for a private room, \$2 for a semiprivate room and \$1.50 in wards. The hospital does not have an outpatient department, and no clinics are in operation by the health department, relief agency or any other organization. Health supervision for the schools, under the control of the board of education, provides for examinations of the students.

The physicians of Pawnee County reported that during 1937 they had given free service to 3,000 persons, and the dentists that they had given free care to 300 persons. The hospital provided services to 143 free patients, 499 pay or part-pay patients and to twelve public charges, which made a total of 1,430 patient days of hospital care for free patients, 4,234 for pay or part-pay patients and 1,500 for public charges. The

Nemaha County

In Nemaha County during 1937, 650 persons were given free services by the physicians and 225 by the dentists. The hospital provided care for 250 pay or part-pay patients, forty public charges and eighteen free patients, which made a total of 1,560 patient-days for pay or part-pay patients, 290 days for public charges and 340 days for free patients. The rates for private rooms are \$3.50 a day, semiprivate \$3. The pharmacists provided forty-five free prescriptions and 150 prescriptions at cost or reduced fees. All the pharmacists reported an increase in the sale of medicine on physicians' prescriptions for the year 1937 as compared with 1936 in relation to the number of sales of home remedies or "patent" or proprietary remedies.

All indigent persons needing medical services may receive the services from the local hospital or physicians, who are then paid by the county relief commissioner. Indigents with serious illnesses are sent to the state university hospital, and the state also maintains institutions for the blind, deaf, crippled children, tuberculous patients and the feeble-minded, to which the county sends suitable cases. In determining the indigence of a person the county relief commissioner investigates a person's financial condition.

It was estimated that 400 persons requested medical care from the health department, and in every case they were provided with the necessary medical services. No persons were reported in need of medical care who did not receive such care by the relief agencies, physicians, dentists, nurses or hospitals.

All the physicians perform preventive medical services in private practice and for the health department. Of each thousand children born alive during 1937 it was estimated that 200 were immunized against diphtheria. All births were attended by a physician or a midwife, but only a small percentage of the children who entered school for the first time in 1937 were successfully vaccinated against smallpox.

Medical Care in Nance County

From Nance County it was indicated that during 1937 the hospital cared for 168 pay and part-pay patients, thirty-two public charges and seven free patients for a total of 1,042 patient-days of hospital care. The bed occupancy during 1937 was 96 per cent. The minimum daily rate is \$3 and the maximum is \$4. During this period physicians estimated that they gave

free services to 812 persons and the dentists to 145 persons. Pharmacists provided 150 prescriptions without charge and 150 at cost or reduced fees.

Persons in need of medical care, but unable to pay for it themselves, were provided for by the county. The county agents in charge of relief determine whether they are entitled to county aid for medical services, and they stated that accidents and sudden illnesses made up the greatest expense for the county with regard to medical care. There were no instances of medical care being refused to any person by the hospital, physicians or dentists. If a person was unable to pay for medical services, the hospitals and the doctors obtained their fees from the county or state relief agency. A physician or a midwife was in attendance at all obstetric cases.

#### Howard County

From the Howard County summary sheet the following information is obtained: Physicians gave free services to 616 persons, and the dentists to 142 persons. The hospital provided services to forty-five pay and part-pay patients, ten public charges and two free patients. The nurses made eighty-six visits during the year, 50 per cent of them without charge to the patient. The pharmacists compounded 242 prescriptions without charge and 147 at cost or reduced fees. Three pharmacists reported an increase in the sales of medicine on physicians' prescriptions for the year 1937 as compared with 1936 in relation to the number of sales of home remedies or "patent" or proprietary remedies. County relief agencies provided the necessary medicines to persons on the relief rolls.

During 1937 there were no instances of persons in need of medical care but unable to obtain it. County relief agencies, with the aid of state and federal funds, provided medical care to all persons in the county needing medical treatment who were financially unable to secure funds to pay for it themselves. In determining who was entitled to receive county aid for medical services, the county relief agency investigated the applicants' financial status.

#### COMMENTS ON CONDITIONS

Six of the seven physicians performed preventive medical services in private practice and four performed preventive services for the county relief agency. The board of education provides health supervision and examinations for school children. Comments which accompanied the summary sheet for this county are as follows:

A comment from a dentist seems to cover the whole situation here very well:

I believe that people as a whole are being cared for quite well even in these times of financial stress. Surely they are getting far better attention than they ever could under a system of socialized medicine, where there would be no end of red tape and professional quackery. A professional man in these days at least does what he thinks is right in order to uphold his reputation, which is a very valuable asset. Under any system of governmental salaries or cut fees the professional standards can only sink to a new low. Of course, people kick against the medical professions but they haven't seen socialized medicine yet or they would have something to kick about.

The following is a summary brought out by the others:

1. The less interference with the profession, the better the morale of both patients, public and doctors.
2. Low income groups as WPA need plans by which they can receive medical services and then pay for them. Inability to pay and not the doctor's refusal to care is reason why many do not seek attention sooner.

3. Local hospital facilities not adequate.

4. The need for free medical services has multiplied during the last few years. Can be supplied through proper arrangements with county boards. Preventive inoculations for indigent cared for through schools and P.-T. A. organizations.

5. People are receiving medical service now and the professions are giving time freely to all that are in need. Public funds should be applied to help both the patient and the doctor, dentist and nurse.

6. Medical services should be supplied to all but the morals in the recipient and his initiative are held on a higher plane where a financial interest is involved. No cases turned down regardless of finances.

#### Franklin County

Franklin County reports that 237 persons were provided free services by physicians and fifty-six by dentists. Pharmacists made up 286 free prescriptions and 151 prescriptions at cost or reduced fees. Indigent persons in need of hospitalization are sent to the university hospital in Omaha. Four persons were reported to have been unable to receive hospital care there because the hospital was overcrowded. Because of lack of funds 100 persons, mostly dental patients, were reported unable to obtain necessary care. This made a total of 104 persons in the county unable to obtain medical, dental or hospital care during 1937. All the physicians reported that they were active in performing preventive medical services in private practice and for welfare agencies.

With regard to medical care for the indigent, the report stated that up to three months ago the county guaranteed to pay the bills of the indigent for necessary medical care. Hospitalization cases were sent to the state hospital at Omaha. Now Franklin County has contracted with the Brewster Hospital, at Holdrege in Phelps County, to handle all the indigents in need of medical care. This arrangement does not provide the indigent with free choice of physician or hospital, and the county pays the same rates for hospital services as it was charged by any of the other nearby hospitals. The resettlement agency of the federal government will pay one half of the bill for medical services received by its clients provided the fees are reduced from 50 to 75 per cent. At the present time the county has spent all the funds apportioned for medical care for the whole year. A new state law prevents the county from contracting any debts, and consequently physicians must continue to provide the indigent with necessary medical care with no remuneration from the county. It is further stated that there are about 2,500 persons on relief in this county and that, unless the county makes a different arrangement whereby it will pay adequate fees for medical care rendered to the indigent and also provide these persons with free choice of physician and hospital, it will be impossible for the physicians to earn enough to cover their living expenses.

The following comments will indicate the necessity for the county to assume the responsibility of paying for medical care of the indigent.

#### 1. Physicians and Dentists:

(a) There is need for much restorative work on teeth. Indigent cases should be paid through a local county agency.

(b) Care of indigents is usually paid by the county from the poor aid fund, although such pay is slow in forthcoming and very often inadequate.

(c) Pay through county, resettlement and other governmental agencies is slow and usually at a greatly reduced fee.

(d) Poor crops prevent many people from getting or seeking medical care because of insufficient funds. These people are not acutely ill but are not well. The county and other agencies will take care only of persons who are seriously ill. Other

persons cannot be taken care of by county funds because the county itself is usually financially embarrassed. If the county could be provided with adequate funds, it would be able to take care of the pay for indigent cases.

(c) Resettlement and other governmental agencies expect physicians to do work at greatly reduced rates while the employees of these agencies are all getting better than average salaries. I believe the county should be allotted funds to be used entirely through the local county agency for cases recommended by the local physician.

## 2. Pharmacists:

(a) Should be worked out by medical and pharmaceutical agencies themselves.

(b) Should have more doctors in small towns, since going to another town or calling in a doctor from another town involves a much greater expenditure.

(c) The doctors and druggists should get at least some of their money in caring for the indigents from the government or state.

(d) Provide the county with adequate funds and the whole thing could be handled very nicely by our doctors and druggists. But we do not want any socialized medicine.

## In Northwestern Nebraska

The Northwest Nebraska County Medical Society, which includes the three counties of Sioux, Dawes and Sheridan, reported on only two counties, Sioux and Dawes. The board of education provides health inspection for school children, and eight physicians perform preventive medical services in private practice. It is estimated that 60 per cent of the children who entered school for the first time in 1937 were successfully vaccinated against smallpox. Free medical services were provided for 260 persons, and free dental care was given to seventy-one persons.

There is no standard arrangement or procedure used by the county to determine a person's inability to pay for medical services or to provide relief clients with the necessary medical care. The individual physician or dentist provides free medical care to all indigent families requesting such care whom he believes to be

deserving of free services. The known chronic indigents and malingerers are unable to secure any further medical care except in emergency cases. The county does not provide any clinic or hospital services for the indigent. Even under these adverse conditions, physicians and dentists believe that no deserving person has been denied the necessary medical or dental care during 1937; however, the Red Cross agency reported ten such cases.

No comments were attached to the summary sheet but the county medical society attached the following recommendations pertaining to the need and method of providing and paying for medical services to the large number of people on relief.

## Recommendations:

1. Direct appeal to the physicians in smaller communities, by representatives of organized medicine to organize for economic reasons as well as educational. Technical articles and talks do not appeal to many physicians in smaller towns. Stress economic value of united effort.

## 2. Publicize:

(a) Physicians' investment in education, overhead expense and hours of work.

(b) Rapid advance in medical knowledge through research—requiring study, "refresher" courses and postgraduate work.

(c) Necessity of public accepting responsibility for health of the indigent.

(d) The right of physicians and dentists to expect pay for services the same as laborers, merchants, relief and social workers and/or politicians.

(e) The right of each physician or dentist to accept or reject service to indigents on a reduced fee basis.

(f) The right of each patient to select his own physician.

(g) The value of preventive medicine and medical supervision of youth.

3. Supply necessary medical and dental care to the indigent through local agencies in cooperation with organized medicine and dentistry.

4. Keep service on a fee basis so that better and more complete service will be encouraged.

## TRIBUTES TO PHYSICIANS

### GORDON B. MAURER

Amidst the tumult and shouting relative to the physician and his work there continue to appear in various newspapers throughout the nation tributes to doctors who have served valiantly in their careers. Recently a young physician, Dr. Gordon B. Maurer, died in Margaretville, N. Y. The *Catskill Mountain News* contained this tribute to him and to his work:

### MOUNTAIN DEW

Thirteen years ago there came here a city chap, trained in one of the great universities.

The other members of his class went to "big towns."

He, with the best records of them all, wanted to begin the practice of medicine in a country village.

He had compiled a list of prospective communities. He looked over several and chose us.

An untried city college boy—with magic hands, a keen vision, and uncanny knowledge of both the human body and the soul which activates it.

Soon after arrival he was called upon to care for a life given up as lost. He saved it.

He began to save others. He worked day and night. When he did not have proper apparatus or appliances he built some. When the snows kept him from patients he constructed a snowmobile.

Neither storm nor night nor mud nor snow kept him from the sick.

He took people into his home. It became a veritable hospital. The fame of the boy spread throughout the section. Men and women from all walks of life asked for his attention.

The community built a hospital that he and others might the better care for those who needed care, medication and operation.

He continued. When a tired body all but gave up he took a year out and returned to Yale for special work that he might come home and serve better.

He had tired of city pastimes. The lure of the country had been breathed into his soul. Camp, rod and gun, open fires, life in the great outdoors gave zest, relief, happiness.

He loved our hills, our mode of life; he knew our ambitions, he smiled at our shortcomings.

He gave freely, much of the work he did was without charge. Few knew the extent of his help to those who needed help. He served as few had ever served here before.

He was physician, parson, priest, confessor—we told him both our physical and mental troubles and he put us back on the road to reason and living.

Thirteen years he served. It was a life work worth while. Today our hearts are numb at his loss, our senses befogged to know how to live without him. May we turn from the tragedy of the golden Indian summer morning that knew his death.

And in the bleak days of the approaching Thanksgiving season thank God for those thirteen years.

Yours truly,  
The Mountaineer.

ROY G. WERNER

In Akron, Ohio, there died not long ago Dr. Roy G. Werner. The following tribute, written by Anthony Weitzel, appeared in the Akron (Ohio) *Beacon Journal*, under the column headed "The Town Crier." (Several paragraphs that appeared in the original publication have been omitted.)

There is nothing I can write here that would add to the beauty or the stature of the glorious human monument that was the life of Dr. Roy G. Werner.

I can only echo the grief that lives today in the hearts of those hundreds of mothers and fathers of Akron who owe their most priceless gifts to his great skill.

I know that grief. Saturday night when I got home my wife was at the telephone, her eyes filled with tears. She said "Dr. Werner is dead!"

Bruce played at her feet, absorbed in the mechanics of a toy truck. We stared at the boy, my wife and I, and our thoughts went back to a chill February dawn, nearly four years ago.

There was no Bruce then. There was only a frantic newspaperman pacing the corridors of City Hospital and a sweet courageous girl somewhere upstairs bravely entering her hour of travail. . . .

After a long, long time, the zero hour came, very suddenly. The telephone girl called me from my pacing. She said "Your wife has just been taken into the delivery room." Then for an awful space there was no word.

The minute hand on the corridor clock seemed to hang motionless against its white face. The world stood still. Then the phone rang and the girl said "It's a boy . . ."

I couldn't believe it for a long moment. Then I raced upstairs. The girl slept, wan and white, on a wheeled cot. A precious little bundle in a nurse's arms made strange gasping noises.

Dr. Werner, still in his white hospital clothes; leaned against the delivery room door, his face drawn with exhaustion.

He said, softly, "Well, I guess we made it . . ."

I felt a twinge of pity for him then; he seemed so utterly spent. He seemed to have poured his very soul into the battle for the life of that little bundle in blankets.

I said to him "I guess you'll be glad to get home and go to bed!"

"Oh," said Dr. Werner, "I've got another delivery coming along in a little while."

That was the doctor's life, as it must be the life of all good physicians. Rich women and poor came to him, with their precious unborn, and to each he gave the same full measure of devotion.

Day after day, year after year, he threw his skill and his strength and his great heart into the fight against death. Nearly always he won, but each victory took its toll of him. Each time he brought a new life into the world he literally gave a part of himself as a hostage to death.

So, unselfishly and humbly, he built his monument, that must live as long as the memories of a generation of mothers. And because he gave so greatly of himself, death came early to claim its hostage, a great and kindly man.

## THE COOK COUNTY HOSPITAL

### A Statement by the Council on Medical Education and Hospitals

Widespread interest in the standing of the Cook County Hospital seems to warrant a review of the events of the last few years as far as they concern relationship between the hospital and the American Medical Association.

The Council on Medical Education and Hospitals in February 1935, after nearly a year of fruitless correspondence with the officers of the hospital and the Civil Service Commission, withdrew from the Cook County Hospital its approval as far as the training of interns is concerned.

In June 1937, in order to protect those interns who received appointments subsequent to February 1935, the Council granted approval to the Cook County internships for a period of one year from July 1, 1937. On July 1, 1938, such approval automatically lapsed.

In the meantime the County Board appointed a Survey Committee consisting of:

Dr. Irving S. Cutter, dean of Northwestern University Medical School and Superintendent of Passavant Hospital, chairman.  
Miss Veronica Miller, superintendent of Henrotin Hospital.  
Rev. John W. Barrett, diocesan director of Catholic hospitals.  
Dr. A. C. Bachmeyer, director, University of Chicago Clinics.  
Mr. Asa Bacon, superintendent of Presbyterian Hospital.  
Mr. Charles A. Wordell, director of St. Luke's Hospital.

The personnel of this committee inspired the highest confidence and gave to its conclusions unimpeachable authority. With these recommendations the Council found itself in fullest accord.

One of these recommendations concerned the appointment of a Citizens' Advisory Committee composed of well known public spirited men to which the County Board might look for advice in all matters pertaining to the organization and operation of the Cook County Hospital. Such a committee was duly appointed.

The Survey Committee called attention to the fact that the professional services in the hospital had not been brought up to present day standards, that the records of patients were inadequate and that there was need for a more systematic

review and analysis of clinical work. Interns were given large responsibilities without sufficient guidance from older and more experienced men, the nursing service was inadequate and the management of the outpatient department was unsatisfactory. In the maintenance of the physical plant many deficiencies were noted. In the judgment of the committee, steps should be taken immediately to (a) provide capable and adequate management, (b) relieve the acute shortage of nursing service in certain wards, (c) give effect to a comprehensive program of maintenance and improvement of equipment essential to the proper care of patients, (d) provide essential new equipment and supplies as required for the care and treatment of patients, (e) give careful consideration to allocating various services throughout the hospital to the approved and accepted medical schools and also a service to be staffed by physicians who have had the examination as required but who may not be members of the faculty of any of the approved and accepted medical schools, (f) promote economies and improvements in operation in all departments and (g) develop a comprehensive long range planning program to care adequately for the indigent hospital needs of Cook County.

Of all the recommendations of the Survey Committee, however, the most important was the requirement that a trained and experienced hospital administrator be appointed as the directing head of the County Hospital. After unsuccessful efforts to secure the services of a well qualified hospital director, the board appointed as warden a retired army officer, Brigadier General Manus McCloskey. The most serious obstacle in the way of getting an administrator with the requisite training and experience was the Illinois statute governing the appointment of "warden." Until such time as the state law can be amended so as to provide satisfactory tenure and eliminate a residence requirement for this position, it may be that the appointment of General McCloskey was the best that the County Board could do.

However, under these circumstances it must be recognized that it is absolutely essential that there be immediately provided a full time assistant to General McCloskey who is a physician and who has had successful experience in hospital management. Negotiations to this end are now under way.

## OFFICIAL NOTES

## COUNCIL ON INDUSTRIAL HEALTH

The first Annual Congress on Industrial Health, sponsored by the American Medical Association, will be held Monday and Tuesday, Jan. 9 and 10, 1939, at the Palmer House in Chicago.

The program of the two day session has been arranged as follows:

## OPENING SESSION, MONDAY MORNING, 9:45

*Report of the Council on Industrial Health*

Stanley J. Seeger, M.D., Chairman, Milwaukee.

## SYMPOSIUM ON INDUSTRIAL RELATIONSHIPS

*The Physician in Industry and Organized Medicine*

Irvin Abell, M.D., President, American Medical Association, Louisville, Ky.

*The Physician in Industry and the Employer*

C. D. Selby, M.D., President, American Association of Industrial Physicians and Surgeons, Detroit.

*The Physician in Industry and the Employee*

Loyal A. Shoudy, M.D., Chief of Medical Service, Bethlehem Steel Company, Bethlehem, Pa.

*Industrial Health and the Private Practitioner*

R. L. Sensenich, M.D., Trustee, American Medical Association, South Bend, Ind.

## MONDAY AFTERNOON, 2:15

*The Program of the American College of Surgeons in Industry*

Frederic A. Besley, M.D., Chairman, Committee on Industrial Medicine and Traumatic Surgery, American College of Surgeons, Waukegan, Ill.

*Uniformity in Workmen's Compensation Procedure*

Voyta Wrabetz, Chairman, Industrial Commission, State of Wisconsin, Madison.

*Bases for Cooperation Between Insurance and the Medical Profession*

Ambrose Kelly, American Mutual Alliance, Chicago.

*A Program for Committees on Industrial Health in the State Medical Societies*

A. D. Lazenby, M.D., Chairman, Committee on Industrial Health, Medical and Chirurgical Faculty of Maryland, Baltimore.

## TUESDAY MORNING, 9:30

*The Health and Safety Program of the U. S. Bureau of Mines*

Daniel Harrington, Chief, Health and Safety Branch, U. S. Bureau of Mines, Washington, D. C.

*The Public Health Interest in Industry—Federal, State and Local*

Warren F. Draper, M.D., Executive Officer, U. S. Public Health Service, Washington, D. C.

*Industrial Health Activities by Labor Departments in the Government*

Alice Hamilton, M.D., Consultant on Industrial Hygiene, Division of Labor Standards, U. S. Department of Labor, Washington, D. C.

*Independent Programs of Investigation and Prevention*

W. J. McConnell, M.D., Secretary Industrial Hygiene Section, American Public Health Association, New York.

## TUESDAY AFTERNOON, 2 O'CLOCK

*Industrial Surgery from the General Surgeon's Point of View*

Harry Mock, M.D., Chicago.

## SYMPOSIUM ON MEDICAL SERVICE TO SMALL INDUSTRIAL PLANTS

*Statement of the Problem*

Victor Heiser, M.D., and Donald Shafer, M.D., Consultants, Committee on Healthful Working Conditions, National Association of Manufacturers, New York.

*The Responsibility of the Private Practitioner*

Carey P. McCord, M.D., Director, Bureau of Industrial Hygiene, City of Detroit Department of Health, Detroit.

*Means for Accomplishment*

Glenn S. Everts, M.D., Melrose Park, Pa.

*Methods of Appraisal*

L. D. Bristol, M.D., Health Director, American Telephone and Telegraph Company, New York.

## HEARINGS BEFORE THE GRAND JURY IN WASHINGTON

The following additional witnesses, all of Washington, D. C. are reported to have appeared last week before the Special Grand Jury in Washington: Dr. Claude C. Caylor, associate professor of radiology, Georgetown University School of Medicine; Dr. John H. Lyons, Emergency Hospital; Dr. Charles S. White, professor of surgery, George Washington University School of Medicine, and Dr. Leon A. Martel, professor of gynecology, Georgetown University School of Medicine.

## RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company, entitled "Your Health," began Wednesday October 19 and will run consecutively for thirty-six weeks. The program is broadcast over the Blue network of the National Broadcasting Company each Wednesday at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).<sup>1</sup>

These programs are broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

- December 7. Tuberculosis and the Teens.
- December 14. What Shall We Eat?
- December 21. Hidden Treasures in Foods.

1. Owing to program conflicts, there will be no Chicago broadcast of the network program. Instead, a recording of the program will be broadcast over station WENR at 8 p. m. each Wednesday. This recording will be an identical rebroadcast of the network program broadcast earlier the same day.

## WOMAN'S AUXILIARY

## California

The auxiliary to the Alameda County Medical Association held a meeting October 21 with 100 members present. Mrs. Elizabeth Lossing of the Berkeley police department spoke on "Protective Work with Girls."

The auxiliary to the Orange County Medical Society met October 4 in Santa Ana. Dr. W. W. Roblee, president of the California Medical Association, gave an address on "Modern Trends in Medicine." Dr. Roblee urged members to study all bills and amendments pertaining to medical legislation.

September 17 the auxiliary to the Santa Clara County Medical Society held a social meeting at the home of Mrs. Russell V. Lee, on the campus of Stanford University, honoring Mrs. Clifford A. Wright, president of the state auxiliary. Mr. Clark Cypher, attorney, Palo Alto, discussed "The Humane Pound Act," which appeared as Proposition No. 2 on the ballot,

November 8.—On October 3 the auxiliary met at the Leon Ghetti Tea Room near Los Gatos. Mr. Adron Beene gave an address on "Medical Legislation."

## Mississippi

The auxiliary to the Mississippi State Medical Association is making an effort to acquaint the people of Mississippi with the purpose and the work of the Mississippi State Preventorium at Sanatorium. The auxiliary is sponsoring a statewide essay contest in the public schools of Mississippi. The subject of the essay is "The Preventorium."

## Oklahoma

Dr. L. S. Willour spoke on "The Basic Science Law" at a recent meeting of the auxiliary to the Pittsburgh County Medical Society in McAlester. The auxiliary presented a copy of "The Horse and Buggy Doctor," by Arthur E. Hertzler, to the public library.

## Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

### ARKANSAS

**Two Day Graduate Course.**—The Arkansas Medical Society conducted its fifth two day course of graduate instruction at the University of Arkansas School of Medicine in Little Rock October 12-13. The guest speakers were:

Dr. Leon Bromberg, St. Louis: Syphilis as a Problem in Differential Diagnosis; Present Status of Artificial Fever Therapy.  
Dr. James S. McLester, Birmingham, Ala.: The Newer Knowledge of Nephritis; Subclinical Deficiency Syndromes.  
Dr. Robert F. Short Jr., Dallas, Texas: Intestinal Obstruction; Problems of Surgery of the Right Upper Abdomen.

Among other speakers were Drs. Nicholas T. Hollis and Elizabeth D. Fletcher on "Insulin and Metrazol Shock in the Treatment of Dementia Praecox"; Carl A. Rosenbaum, "Technic for the Injection of Varicose Veins"; Jerome S. Levy, "Mode of Action and Uses of Sulfanilamide"; Ewell I. Thompson, "Scabies and Impetigo: Diagnosis and Treatment"; Robert Q. Patterson, "Tinea: Diagnosis and Treatment"; John N. Compton, "The Truth About Atabrine and Plasmochin," and Jesse D. Riley, State Sanatorium, "Diagnosis and Treatment of Tuberculosis by the General Practitioner."

### CALIFORNIA

**Changes in Health Officers.**—Dr. Morris Krutchkoff has been appointed health officer of Ferndale, succeeding Dr. Joseph M. Brown. Dr. Harold J. Shanks is now health officer of Pleasanton succeeding the late Dr. William D'Arcy Chace. Dr. Ellert E. Lundegaard, Weimar, has been appointed health officer of Colfax to succeed Dr. Ray C. Atkinson.

**Society News.**—Dr. Robert G. Majer, among others, discussed "Abdominal Symptoms in Hyperthyroidism" before the Los Angeles Surgical Society November 25.—A symposium on extrapulmonary tuberculosis was presented before the Trudeau Society of Los Angeles November 22 by Drs. Henry Sutherland-Campbell, David H. Kling, Herman Z. Semenov, Los Angeles, and Hubert T. Wilken, Santa Monica.

### CONNECTICUT

**Lectures on Gastro-Enterology.**—The Fairfield County Medical Association, cooperating with the local medical societies, is presenting monthly lectures on the gastrointestinal tract. Alfred Z. Gilman, Ph.D., New Haven, gave the first lecture in Danbury October 5 on "Mechanics of the Gastrointestinal Tract in Health and Disease." Dr. Zacharias Bercovitz, New York, gave the second, November 8, in Bridgeport, on "The Patient and His Indigestion." The remaining lectures will include:

Dr. John L. Kantor, New York, January 10, in Greenwich, Treatment of Peptic Ulcer and Its Complications.  
Dr. Samuel C. Harvey, New Haven, February 8, in Norwalk, Carcinoma of the Stomach.  
Dr. Isidor S. Ravdin, Philadelphia, March 14, in Stamford, Diseases of the Gallbladder and Bile Ducts.  
Dr. Chester M. Jones, Boston, May 11, in Danbury, Diseases of the Liver.

### ILLINOIS

**Hospital News.**—The cornerstone of the new building for St. John's Hospital was laid in Springfield October 16. The new unit will be twelve stories high with accommodations for 620 patients.

**Society News.**—Dr. Francis L. Lederer, Chicago, addressed the Rock Island County Medical Society in Moline November 8 on "Throat Complications of Interest to the General Practitioner."—Dr. Fred M. Drennan, Chicago, discussed "Diagnosis and Treatment of Irritable Colon" before the Will-Grundy County Medical Society in Joliet October 18. Dr. Jacob P. Greenhill, Chicago, addressed the society November 3 on "Diagnosis and Treatment of Obstetric Hemorrhages."—The McHenry County Medical Society was addressed October 27 by Dr. Philip H. Smith, Evanston, on "Management of Placenta Praevia."—A symposium on intestinal obstruction was presented before the Sangamon County Medical Society, Springfield, November 3 by Drs. Richard F. Herndon, Thomas D. Masters, David J. Lewis and Charles L. Patton, all of Springfield.

### Chicago

**Diphtheria at Hines Hospital.**—A quarantine was placed against the Veterans' Administration Facility in Hines November 27, closing it to visitors following an outbreak of four cases and one death from diphtheria, according to the *Chicago Tribune*. At the time of this report fourteen patients had infectious sore throats. It was stated that six diphtheria carriers were disclosed in the tests that were given to 1,200 staff members and 1,800 patients. The quarantine will be continued until danger of an epidemic is over.

**Dr. Black Appointed Acting President of Board of Health.**—Dr. Robert A. Black, professor of pediatrics, Loyola University School of Medicine, has been appointed president of the Chicago board of health. The appointment is temporary during the absence of Dr. Herman N. Bundesen, who has been granted leave of absence pending the outcome of the government's antitrust action against the milk industry, newspapers reported. Dr. Black has been a member of the board of health since 1935; he also is founder and superintendent of the La Rabida sanatorium in Jackson Park for children with heart disease.

### IOWA

**Annual Clinic.**—The State University of Iowa College of Medicine, Iowa City, presented its annual clinic November 10-11. The program covered fractures of the arm, head injuries and varicose ulcers. Dr. Harry P. Smith, Iowa City, was chairman of the committee on arrangements.

**State-Wide Survey of Gas Gangrene.**—A survey will be conducted in every county in the state by the fracture chairman and the president and secretary of each county medical society to obtain the history of every authentic case of gas gangrene in that county, according to the state medical journal. The work will be under the auspices of the fracture committee of the Iowa State Medical Society. Complete information will be obtained, including the name and age of the patient, the type of injury, whether or not prophylactic serum was given and when given; exact time gas developed; a positive bacterial finding of *Bacillus welchii*; time and exact type of treatment, and the final results showing mortality, duration of treatment, loss of limbs and duration of the disease.

### KANSAS

**Society News.**—At the meeting of the Kansas section of the American College of Physicians in Topeka November 4 the speakers included Drs. Philip W. Morgan, Emporia, on gastric acidity; Norman Reider, Topeka, headaches; Arthur J. Revell, Pittsburg, "Role of the Pituitary Gland in Clinical Medicine"; Frank A. Trump, Ottawa, "The Misuse of Digitalis"; Fred E. Angle, Kansas City, "Gallbladder Dysfunction"; Harold W. Palmer, Wichita, "Case of Acute Idiopathic Hematoporphyria with Acute Ascending Paralysis," and William C. Menninger, Topeka, "Cardiac Neuroses."

### KENTUCKY

**State Medical Election.**—Dr. John W. Scott, Lexington, was chosen president-elect of the Kentucky State Medical Association at the annual meeting in Louisville October 6. Vice presidents elected were Drs. James Duffy Hancock, Louisville; Ewing L. Palmore, Glasgow, and Joseph T. Molony, Covington. Dr. William E. Gardner, Louisville, was installed as president and Dr. Arthur T. McCormack, Louisville, was reelected secretary for a five year term. The 1939 meeting will be in Bowling Green.

**Dr. Abell Awarded Laetare Medal.**—Dr. Irvin Abell, Louisville, President of the American Medical Association and clinical professor of surgery, University of Louisville School of Medicine, was presented with the Laetare Medal of the University of Notre Dame, South Bend, Ind., at special ceremonies November 5. Most Rev. John A. Floersh, archbishop of Louisville, presided and Rev. John F. O'Hara, president of the university, made the presentation. The orator was Rev. Norbett Hoff, professor of philosophy at Notre Dame, and his subject "The Meaning of Leadership."

**New Superintendent of State Mental Hospital.**—Dr. Floyd K. Foley of the staff of the Veterans' Administration Facility, Lexington, has been appointed superintendent of the Eastern State Hospital, Lexington. He succeeds Dr. James L. Vallandigham, who resigned November 1. The change is in accordance with a law enacted at a special session of the state legislature last May with a view to reorganizing the state mental hospitals. As a part of the reorganization Dr. Joseph G. Wilson, formerly of the U. S. Public Health Service, was

appointed director of a new division of hospitals and mental hygiene in the state department of welfare at Frankfort. Appointment of Dr. Foley to the Lexington hospital was recommended by a committee of the Kentucky State Medical Association, according to newspaper reports. The committee included Drs. Arthur T. McCormack, secretary of the state medical association; Irvin Abell, President of the American Medical Association; William E. Gardner, president of the state association, and Arthur C. McCartv. all of Louisville; Ernest B. Bradley, Lexington; Austin Bell, Hopkinsville, and Carl C. Howard, Glasgow. Dr. Foley is a native of Kentucky and graduated from the University of Louisville School of Medicine in 1911. He has been associated with the Veterans' Administration since 1930 and on the staff of the facility at Lexington since 1933.

### MASSACHUSETTS

**Society News.**—The Hampden District Medical Society was addressed in Springfield October 25 by Dr. Henry R. Viets, Boston, on "Acute Lymphocytic Meningitis and Other Virus Diseases of the Central Nervous System."—The first fall meeting of the Worcester District Medical Society was addressed by Drs. Joseph M. Looney on "Determination of Serum Phosphatase and Its Clinical Significance"; James S. P. Beck, "Cause of Death in Newborn," and William G. Moran, "The Pathologist and His Relation to the General Practitioner." The society was addressed November 9 by Drs. Robert S. Palmer on "Bright's Disease and Hypertension" and Maurice B. Strauss, "Anemia: Modern Methods in Diagnosis and Treatment of Blood Dyscrasias." Both are from Boston.

### MINNESOTA

**Personal.**—Dr. Frank L. Jennings, assistant superintendent and associate medical director of Glen Lake Sanatorium, Oak Terrace, for twenty-one years, has been appointed superintendent and medical director of Sunnyside Sanatorium, Oaklandon, Ind., succeeding Dr. Argal E. Hubbard, it is reported. Dr. Jennings has been a clinical assistant professor of medicine at the University of Minnesota Medical School, Minneapolis; he is also a member of the board of trustees of the Hennepin County Tuberculosis Association.

**Society News.**—At a meeting of the Scott-Carver Medical Society in Montgomery October 11 Drs. George D. Eitel, Minneapolis, discussed "Traumatic Surgical Emergencies" and Ernest L. Meland, Minneapolis, urologic emergencies.—Dr. Hubert T. Sherman, Plainview, gave the presidential address before the seventieth annual meeting of the Wabasha County Medical Society in Wabasha October 6 on "Cooperation Within the Society"; other speakers included Drs. Gordon R. Kamman, St. Paul, "Epidemic Encephalitis"; Bernard A. Flesche, Lake City, "Granulocytopenia"; Edward Dyer Anderson, Minneapolis, "Practical Points in Pediatric Practice," and Walter C. Popp, Rochester, Minn., "Roentgen Therapy in Malignant Disease."—Dr. Raymond N. Bieter, St. Paul, discussed "The Chemistry and Therapeutic Use of Sulfanilamide" before the Washington County Medical Society October 11.

### MISSISSIPPI

**Baylor Faculty Members Address Central Society.**—Members of the faculty of Baylor University School of Medicine, Dallas, Texas, will present the program before the Central Medical Society in Jackson, December 6. The speakers will include:

- Dr. Calvin R. Hannah, Diagnosis and Management of Postoccipital Position and Toxemias of Pregnancy with Related Hypothyroidism.
- Dr. Henry M. Winans, Coronary Occlusion and Treatment of Hypertension.
- Dr. Hugh Leslie Moore, Pediatric Diagnosis and Common Allergic Disorders in Childhood.
- Dr. William B. Carrell, Fractures Involving the Ankle Joint and Osteomyelitis.
- Dr. Charles L. Martin, Developments in Treatment of Cancer with Radiation; A Study of Fallopian Tubes in Sterility.
- Dr. Alfred L. Folsom, Pyelitis in Children and in Pregnancy.
- Dr. Jesse Bedford Shelmire, The Handling of the Common Skin Diseases in Private Practice; Causes and Treatment of Eczema.

### MISSOURI

**Plan for Correlating Committee Activities.**—A plan for correlating committee activity in graduate instruction for physicians and health education for the public was effected by chairmen of the various committees of the Missouri State Medical Association at a meeting in St. Louis October 13. The chairmen of the following committees make up the new committee: graduate course, cancer, conservation of eyesight, fractures, health and public instruction, maternal welfare, medi-

cal economics, mental health, publication, physical therapy, and control of syphilis. The plan will not interfere with the activity of individual committees but will emphasize and control more concentrated discussions on specific subjects, from both lay and medical points of view.

### NEBRASKA

**Society News.**—Speakers before the Lancaster County Medical Society, Lincoln, October 4, were Drs. Hiram Winnett Orr, on "Prevention of Deformity in Arthritis" and Drs. Ephraim Korol and Harry A. Scott, "Etiology of Bronchiectasis."—Sioux City (Iowa) physicians addressed the Fire-Counties Medical Society (Cedar, Wayne, Thurston, Dixon and Dakota counties) in Wayne October 4 as follows: Drs. Jacob N. Lande on "Immunization"; Roy Crowder, "Perineal Repair"; Roland T. Rohwer, "Management of the Irritable Colon," and Howard I. Down, "Ulcers of the Stomach."—Dr. John F. Gardiner, Omaha, addressed the Madison Six County Medical Society, Norfolk, recently on "Recognition and Treatment of Some Endocrine Disorders."—Drs. Robert D. Schrock and Charles A. Owens, Omaha, addressed the Omaha-Douglas County Medical Society October 11 on "Diagnosis of Bone Tumors" and "Value of Heat Therapy in Sulfanilamide-Resistant Gonorrhea" respectively.

### NEW HAMPSHIRE

**Changes in State Board of Health.**—Dr. Charles A. Weaver, Concord and Manchester, has retired after more than twenty years of service with the state board of health as epidemiologist and director of venereal disease control. Dr. Weaver is 83 years old and graduated from the University of Vermont School of Medicine in 1881. Dr. John S. Wheeler, Wolfeboro, will take Dr. Weaver's place temporarily. Dr. Byron H. Farrall, Boscawon, director of the division of maternal and child health and crippled children services, has also resigned and has been succeeded by Dr. Mary Atchison, formerly of Dubuque, Iowa.

### NEW JERSEY

**Campaign Against Appendicitis.**—The Medical Society of New Jersey has begun its second annual campaign to reduce the appendicitis death rate in cooperation with pharmacists and school authorities. The society has sent 60,000 stickers to school physicians for distribution to students. The stickers bear a warning against taking laxatives in the presence of abdominal pain, advise calling the family doctor and explain that pain, cramps or soreness that lasts more than four hours is usually serious. Large placards with the same warning will be distributed to pharmacists, who will be asked to post them conspicuously.

**Society News.**—Dr. William T. Lemmon, Philadelphia, addressed the Gloucester County Medical Society, Woodbury, September 15 on "Surgery of the Sympathetic System."—Drs. Edward G. Waters, Jersey City, and Theodore Neustaedter, New York, addressed the Passaic County Medical Society, Paterson, September 8, on "Injuries to the Birth Tract During Parturition" and "Modern Concept of the Relationship and Value of Endocrines in Obstetrics" respectively.—Dr. Leonard Averett, Philadelphia, addressed the Atlantic County Medical Society October 14 on "Advantages of the Vaginal Operative Approach to Pelvic Pathology Over the Abdominal Route" and Dr. Watson B. Morris, Springfield, "Objectives and Administrative Policies of the Medical Society of New Jersey."—Dr. Howard C. Taylor Jr., New York, lectured at Aurora Institute, Morristown, November 6, on ovarian and pituitary therapy.

### NEW YORK

**Albany Alumni Meeting.**—The Alumni Association of Albany Medical College held its annual Alumni Day December 1 with Dr. Frank H. Lahey, Boston, as the guest speaker on "Newer Surgical Entities." Both operative and dry clinics were presented at the hospital. In the afternoon there were teaching demonstrations in the college.

**Changes in State Health Department.**—Dr. Ernest L. Stebbins has been made assistant commissioner of the state department of health in charge of preventable diseases, the department announces. Dr. James E. Perkins is now director of communicable diseases and Dr. Paul A. Lembcke epidemiologist in the division of communicable diseases. The following have been appointed district health officers in the districts indicated: Drs. Samuel A. Hyman, Buffalo, to the Utica dis-

trict; Franklyn B. Amos, Batavia, to the Amsterdam district; Harry L. Chant, Kingston, the Middletown district, and Hollis S. Ingraham, Albany, the Kingston district. Dr. Frank E. Coughlin, Albany, has been promoted to the position of district state health director in charge of the eastern districts.

#### New York City

**Annual Hospital Fund Drive.**—The United Hospital Fund is conducting its annual drive for funds to carry on the work of the ninety-two voluntary hospitals associated with the fund. A minimum of \$2,523,179 is needed, it was announced. Mr. Colby M. Chester is chairman of the campaign.

**Tuberculosis Conference.**—A clinical session on chronic pulmonary diseases under the auspices of the Tuberculosis Sanatorium Conference of Metropolitan New York will be held at Cornell University Medical College December 14. The speakers will be Drs. Ida Levine, on "Bilateral Simultaneous Pneumothorax"; Abraham V. Shapiro and Foster Murray, "Clinical Application of Tomography to the Study of Pulmonary Tuberculosis," and Daniel A. Mulvihill, "Late Results of Apicolytic Thoracoplasties."

**Society News.**—Dr. Ira Cohen addressed the New York Surgical Society October 19 on "Acute Epidural Spinal Infection."—Drs. Foster Kennedy, Emanuel D. Friedman and Orman C. Perkins addressed the Association for the Advancement of Industrial Medicine and Surgery October 19 on "Head Injuries."—A symposium on macrocytic anemias was presented at a meeting of the Medical Society of the County of New York October 24 by Drs. George R. Minot, Boston; Cornelius P. Rhoads, New York; Maurice B. Strauss, Boston, and Cyrus C. Sturgis, Ann Arbor, Mich. The program was arranged in conjunction with the Graduate Fortnight of the New York Academy of Medicine.

**Expansion of Kings County Hospital.**—The city planning commission has included in its budget funds for expansion of Kings County Hospital, Brooklyn, on a large scale, the department of hospitals announced November 3. The items approved include a building for chronic patients, \$2,735,500; a building for patients with mental or emotional disturbances requiring temporary diagnostic facilities, \$1,430,000; a building to relieve overcrowding in the clinics, \$1,087,500, and a central hospital laboratory \$400,000. Although the hospital's capacity has been reduced by 275 beds during the past year by demolition of the old main building, the hospital population was 2.5 per cent larger than in 1937, it was reported.

**Medical-Dental Meeting.**—The eighth annual medical-dental convention arranged by the Joint Committee of the Organized Medical and Dental Professions of New York will be held December 5 at the Hotel Pennsylvania. Papers will be presented at the morning session by the following:

Theodor Rosebury, D.D.S., Primary and Secondary Factors in Dental Caries in Animals and Man.

Thomas A. Cook, D.D.S., Oral Infections: Factors That Influence the Diagnosis and Treatment.

Dr. Nathan Rosenthal, Lesions of the Oral Mucous Membranes in the Various Types of Blood Dyscrasias.

Dr. Walter F. Watton, The Pediatrician's Role in Prevention of Caries.

A clinical session will be held in the afternoon, when cases will be shown from Long Island College of Medicine, Cornell University Medical College and Mount Sinai Hospital.

#### NORTH CAROLINA

**Personal.**—Dr. David E. Plummer, Mocksville, has been appointed to take charge of a venereal disease clinic in Durham, a full time position.—Dr. Albert F. Houck, Lenoir, has presented his medical library to the Caldwell County public library, where a special section will be set aside for it.

**Society News.**—Dr. Porter P. Vinson, Richmond, Va., addressed the Forsyth County Medical Society, Winston-Salem, October 11 on bronchoscopy.—Dr. John P. Peters, New Haven, Conn., addressed the Buncombe County Medical Society, Asheville, October 14 on "Clinical Problems in Salt and Water Metabolism." Dr. John T. Saunders addressed the society October 3 on "Common Functional Foot Disorders."

#### OHIO

**Joint Obstetric Meeting.**—Obstetricians of Pittsburgh and Buffalo were guests of the obstetric and gynecologic section of the Cleveland Academy of Medicine November 7. Clinics, demonstrations and discussions were held at MacDonald House and St. Luke's Hospital during the day and in the evening Dr. William E. Caldwell, New York, gave an address on "X-Ray Pelvimetry."

**Annual Lecture Course in Lima.**—Drs. Carl E. Badgley, Ann Arbor, Mich., and Charles A. Doan, Columbus, conducted the annual postgraduate course sponsored by the Academy of Medicine of Lima and Allen County September 22-27. Dr. Badgley discussed pain low in the back, ununited fractures, epiphyseal fractures of the elbow joint and soft tissue lesions of the upper extremities. Dr. Doan's subjects were iron metabolism and the simple anemic states, macrocytic anemias, the splenopathies, role of the white blood cells, the lymphadenopathies and new approaches to recognition and control of the leukemic states.

**Conference on Legislative Activities.**—A conference of legislative committeemen and officers of county medical societies was held in Columbus October 2. Dr. Daniel C. Houser, Urbana, chairman of the subcommittee on legislation of the Ohio State Medical Association, presided. The chief speakers were Drs. Roscoe L. Sensenich, South Bend, Ind., a Trustee of the American Medical Association; Barney J. Hein, Toledo, president of the state association; Louis Howard Schriver, Cincinnati, councilor of the first district; Carl W. Sawyer, Marion, a member of the subcommittee on legislation, and Mr. Charles S. Nelson, executive secretary.

#### PENNSYLVANIA

**Hospital News.**—Allentown Hospital recently opened a plastic surgery clinic under the direction of Dr. Kerwin M. Marcks, Emaus.

**County Society Graduate Lectures.**—The Butler County Medical Society sponsored a series of lectures at the Butler County Memorial Hospital, Butler, October 13 to November 19. The series was arranged by the committee on graduate education of the Medical Society of the State of Pennsylvania. Following was the schedule:

Dr. Roy W. Scott, Cleveland, Diagnosis and Management of the Common Types of Cardiovascular Disease.

Dr. Edward Weiss, Philadelphia, Diseases of the Kidney.

Dr. Harry E. Bacon, Philadelphia, Diagnosis and Treatment of the More Common Pathologic Conditions of the Anus, Rectum and Colon.

Dr. Arthur J. Skeel, Cleveland, Practical Aids and Procedures in the Field of Obstetrics.

Dr. Harold L. Mitchell, Pittsburgh, Neurological Diseases—Emphasizing the Neuroses.

Dr. Richard A. Kern, Philadelphia, Allergy—Demonstration of Diagnostic Procedures.

#### Philadelphia

**Tuberculosis Conference.**—The annual Philadelphia Tuberculosis Conference was held November 15 at the Bellevue-Stratford under the auspices of the Philadelphia Health Council and Tuberculosis Committee. Dr. John Alexander, Ann Arbor, Mich., addressed a luncheon meeting on "Relation of Collapse Therapy to the Control of Tuberculosis" and a medical session in the evening on "Role of Lobectomy and Pneumonectomy in Management of Tuberculosis."

**Dr. Bond Resigns Hospital Posts.**—Dr. Earl D. Bond, director of the Institute for Mental Hygiene of the Pennsylvania Hospital and head of the department of nervous diseases at the hospital, has resigned from these positions to devote his time to research, it is reported. He will be succeeded by Dr. Lauren H. Smith, a member of the executive staff of both units since 1926. Dr. Bond will continue as vice dean for psychiatry and professor of psychiatry at the University of Pennsylvania Graduate School of Medicine.

#### WASHINGTON

**Northwest Orthopedic Society.**—The annual meeting of the Pacific Northwest Orthopedic Society was held in Tacoma October 1. The following officers were elected: Drs. Donald M. Meekison, Vancouver, B. C., president; Donald A. Murray, Seattle, vice president, and John R. Naden, Vancouver, secretary.

**Committee on Industrial Health.**—Dr. Hubbard T. Buckner, Seattle, has been made chairman of a new committee on industrial health, appointed by the president of the Washington State Medical Association, Dr. Harry E. Rhodehamel, Spokane. Other members of the committee are Drs. Samuel L. Caldbick, Everett, and Richard J. Bailey, Spokane.

#### WEST VIRGINIA

**More Diseases Made Reportable.**—The state Public Health Council at a meeting October 31 in Bluefield passed a regulation requiring that pneumonia, typhus fever, undulant fever and diarrhea of the newborn be reported by physicians. The rule went into effect November 1.

**The Schwinn Lecture.**—Dr. Howard R. Sauder, Wheeling, gave the annual Schwinn Lecture of the Ohio County Medical Society, Wheeling, November 11. His subject was "The Clinical Variants of Coronary Arteriosclerosis." The Schwinn lecture honors Dr. Jacob Schwinn, long a member of the society and now 84 years old.

**Society News.**—Drs. Alfred Spates Brady Jr. and Russel Kessel, Charleston, addressed the Logan County Medical Society recently on "Management of Congestive Heart Failure" and "Treatment of Artificial Menopause" respectively. —The annual joint meeting of the Preston and Monongalia county medical societies was held in Hopemont recently with Dr. Ray M. Bobbitt, Huntington, as the speaker, on "Medical Management of Urinary Tract Infections." —Dr. Robert V. Funsten, Charlottesville, Va., addressed the Ohio County Medical Society October 14 on "Some Problems in Fracture Treatment."

### WISCONSIN

**District Meetings.**—The Tenth Councilor District of the State Medical Society of Wisconsin held a meeting September 29 in Eau Claire with the following speakers: Drs. Jennings C. Litzenberg, Minneapolis, on "Toxemias of Pregnancy"; William S. Middleton, Madison, "Anemias, Their Interpretation and Treatment"; Carl W. Waldron, Minneapolis, "Fractures of the Face and Jaw," and Fred S. Cook, Eau Claire, "Foreign Bodies in the Food and Air Passages." —The Eleventh Councilor District met in Superior recently in conjunction with the Interurban Academy of Medicine. The speakers were Drs. Francis D. Murphy, Milwaukee, on cardiac disease; James C. Sargent, Milwaukee, conservative surgery of the kidney; Robert E. Burns, Madison, orthopedic surgery; John E. Gonce Jr., Madison, abdominal disease in children, and Raymond G. Arveson, Frederic, adequacy of medical care in Wisconsin.

### GENERAL

**Meeting of Anesthetists.**—The annual meeting of the American Society of Anesthetists will be held December 8 at the building of the College of Physicians of Philadelphia. The speakers will be Drs. Lincoln F. Sise, Boston, on "A Pioneer's Conception of Anesthesia as a Specialty for the Young Physician of Today" and Ralph M. Waters, Madison, Wis., "The Management of the Anesthetic Period as a Means of Preventing Undesirable Effects During Convalescence." Dr. Paul M. Wood, New York, is secretary of the society.

**Warning of Swindler.**—Illinois physicians have complained that a man claiming to represent "Westcot and Company" or "Sherman and Company" of Chicago has taken orders for surgical supplies, collected for them at the time and failed to deliver the goods. Letters sent by these physicians to the addresses given for these concerns have been returned with the notation "No such address" and the firms were not listed in the Chicago telephone directory. The impostor was described as being from 45 to 55 years old, 5 feet 8 inches tall, weighing about 135 pounds and having light brown hair and smooth face. In one instance he gave his name as "Mr. Westcot."

**Index for Psychologic Literature.**—The American Psychological Association recently appointed an advisory committee to supervise the compilation of the Psychological Index now under way with the assistance of the Works Progress Administration. Albert T. Poffenberger Jr., Ph.D., of Columbia University is chairman of the committee and the members are Karl M. Dallenbach, Ph.D., Cornell University, Ithaca, N. Y.; Chauncey M. Louttit, Ph.D., Indiana University, Bloomington, and Raymond R. Willoughby, Ph.D., Brown University, Providence, R. I. The committee will advise in the direction of the project and assume responsibility for all decisions pertaining to the actual index and for psychologic nomenclature, it was said.

**Fellowships Available in Medical Sciences.**—Fellowships in the medical sciences, administered by the Medical Fellowship Board of the National Research Council, of which Dr. Francis G. Blake of Yale University is chairman, will be available for the year beginning July 1, 1939. These fellowships are open to citizens of the United States and of Canada who possess an M.D. or a Ph.D. degree. They are intended for recent graduates and not for persons already established. Fellows will be appointed at a meeting of the Medical Fellowship Board about March 1. Applications to receive consideration at this meeting must be filed on or before Jan. 1, 1939. Appointments may begin on any date determined

by the board. For further particulars concerning these fellowships, address the secretary of the Medical Fellowship Board, National Research Council, 2101 Constitution Avenue, Washington, D. C.

**International Neurological Congress in 1939.**—The Third International Neurological Congress will be held in Copenhagen, Denmark, Aug. 21-25, 1939, under the presidency of Prof. Viggo Christensen. Three days of the congress will be devoted to the following symposiums: "The Autonomic Nervous System with Special Reference to the Endocrine System," "Heredofamilial Disease, Especially from the Genetic Aspect" and "Neurological Aspects of the Avitaminoses." One day will be given over to ten minute papers by active members of the congress. Those desiring to present such papers must furnish to the secretary for the United States a title and an abstract of not more than 200 words on or before March 1, 1939. The committee for the United States will tentatively accept the papers and forward them to the Danish committee for final action. Proposers of papers will probably be notified about May 1, 1939, whether the papers have been accepted. Membership in the congress will be comprised of active and associate members. Applicants for active membership must belong to some national or local neurologic, psychiatric or neuropsychiatric association or society and must have an endorsement of their applications by the local association or by some neurologist or psychiatrist known to the United States committee. The fee for active membership is \$8. Members of families, physicians in other specialties and nonmedical persons engaged in related fields of activity may apply for associate membership, the fee for which is \$4. The American Express Company is the official travel agent. The members of the United States committee are Drs. Bernard Sachs, New York, chairman; Henry Alsop Riley, New York, secretary; Foster Kennedy, New York; John F. Fulton, New Haven, Conn.; Stephen W. Ranson, New York, and Stanley Cobb, Boston. Dr. Riley's address is 117 East Seventy-Second Street, New York. Canadians interested in attending should communicate with Dr. Wilder G. Penfield, 3801 University Street, Montreal, Que.

**Review of Causes of Death.**—The U. S. Bureau of the Census recently issued a detailed tabulation of deaths that occurred in the United States in 1936 by sex, race and age. Included in the report was a table showing the number of deaths and the death rate each year since 1900, when the original death registration area was established. Over the span of years the rate has decreased from 17.6 to 11.5. Originally the registration area contained only ten states; since 1933 statistics have been collected from all states. Diseases of the circulatory system caused the greatest number of deaths in any large group. Among specific causes were chronic myocarditis and myocardial degeneration 110,654, chronic endocarditis 50,529, disease of the coronary arteries 48,622 and angina pectoris 17,760. Cancer and tumors caused 149,126 deaths, with most numerous group being cancer of the digestive tract, 68,239 deaths. Cancer of the uterus caused 16,280 deaths. Infectious and parasitic diseases caused 148,798 deaths. Included in this group were 3,098 from typhoid, 22,889 from influenza, 3,020 from epidemic cerebrospinal meningitis, 71,527 from tuberculosis and 12,612 from syphilis. There were thirty-five deaths from smallpox. Diabetes, included in a miscellaneous group, were caused 30,406 deaths. Diseases of the nervous system were responsible for 143,543 deaths, of which 103,560 were attributed to cerebral hemorrhage. Another large group is diseases of the respiratory system, which caused 134,920 deaths. Of these 119,055 were listed under pneumonia. Notable in the classification of diseases of the digestive system were appendicitis with 16,480 deaths and cirrhosis of the liver with 10,587. Ulcer of the stomach caused 5,987. Violent and accidental deaths accounted for 138,775 persons. There were 18,294 suicides, 13,522 of them among men; firearms were used in 6,771 cases. There were 10,232 homicides. Lives lost in automobile accidents amounted to 35,761; in addition, 1,697 persons died in railroad and automobile collisions and 269 in street car and automobile collisions. There were 26,673 deaths from injuries received in falls, 6,973 from drowning, 6,793 from burns and 1,807 from accidental gas poisoning.

### Deaths in Other Countries

Sir James Barr, vice president of the British Medical Association and for many years a leader in prison reform, died in London November 16, aged 89. —Dr. Jane H. Walker, who is said to have been the first physician to introduce the open air treatment of tuberculosis in England, died in London November 17, aged 79.

## Foreign Letters

### LONDON

(From Our Regular Correspondent)

Nov. 5, 1938.

#### Radium Therapy

The report of the Radium Institute for 1937, which has just been published, shows the progress which has been made during the year.

##### CARCINOMA OF THE CERVIX UTERI

The technic has been altered by increasing the content of the uterine applicator; the most distal tube has been raised from 10 to 15 mg., the other two tubes remaining at 10 Gm. Thus the total dose is increased to 9,120 mg. hours. One of the complications considered is invasion of the urinary bladder. Mic-turition symptoms and bimanual palpation were found to be unreliable indications of this. It had been suggested that, when the bladder is definitely involved by a growth, only local and palliative treatment should be given and that cystoscopy is a means of picking out cases not worth treating from a curative point of view. The series of cases now under review does not support this view. Several patients who were considered to have cancer of stage 4 have lived long enough without disease to have warranted full treatment. Recurrences after Wertheim's operation have been found to be worth treating by radiation. Of eighty patients treated between 1925 and 1932, ten survived five years and more, twelve were untraced and one died from other causes. Since 1932, five patients have been treated, of whom three are alive. All these were treated either by vaginal irradiation alone or by this combined with interstitial irradiation to a recurrent mass carried out through the vagina.

##### LIMBAL TUMORS

Good results were obtained in the irradiation of limbal tumors (growths at the junction of the cornea and conjunctiva, most of which are squamous cell epithelioma). There were twenty-eight cases, in most of which contact irradiation was given with unscreened radium for from fifty to sixty minutes. Two further exposures were given at intervals of from six to eight weeks. No case of postirradiation cataract occurred. It has been found that this sequel is confined to treatment by gamma radiation with screened radium for long periods.

##### PITCH WARTS

A large number of cases of pitch warts were treated. These are very common in those who work with gas, tar, pitch and the various oils which are derived from the destructive distillation of coal. They also occur in those who work with the various creosote and anthracene oils. Excepting the scrotum, pitch warts occur on exposed parts of the body—the face, neck, scalp, hands and forearms. They take two forms: the soft villous type, which bleeds easily, and the hard, smooth rounded variety, which is the more common. The latter can often be detected by palpation before they become visible. They then appear as separate conical warts with a black center, usually depressed. If ulceration occurs, it affects only the apex. The importance of pitch warts lies in the fact that if neglected they may develop into epitheliomas. Their prompt removal in the precancerous stage is therefore indicated. Education of the workers in habits of cleanliness and the reporting of any suggestive lesion have reduced the incidence and promoted early treatment. Pitch warts are extremely radiosensitive. They are treated by unscreened radium in flat applicators containing 5 mg. per square centimeter. These are placed in contact with the wart for periods of from eighty to 100 minutes. In almost every case the warts disappear in four or five weeks. In only four of 100 cases was a second application necessary. In only three

cases was the lesion malignant. Two lesions were treated by excision. One, on the forearm, was treated by radon seeds and disappeared. A secondary gland appeared in the axilla three months later and was treated by surface radium. The patient had no further trouble.

#### Birth Rate a Source of Great Anxiety to France

If the present drop in the national birth rate continues, the population of France in fifty years will drop from 40,000,000 to 28,000,000. Deaths exceeded births by 14,000 in 1937, when foreigners were included in the tabulation, and by 30,000 for French families alone. The national birth rate in 1876 was more than 1,000,000, as compared with 616,000 in 1937. During this period the average duration of life has increased from forty-five to sixty years. At the present rate France will lose 100,000 inhabitants a year and in another twenty years the loss will reach 200,000 a year. Meanwhile, in the totalitarian states the birth rate is rapidly increasing. There were 861,000 more births than deaths in 1937 in Italy.

#### French Surgical Congress

The third subject chosen for special reports and discussion at the French Surgical Congress was sarcomas of the muscles and intermuscular septums of the extremities. The reporters were Drs. Moulouquet of Paris and Pollosson of Lyons. The reports included an analysis of 119 personally observed cases; the condition had arisen in the intermuscular fibrous tissue in forty-three cases and in the muscles in thirty-seven. Sarcoma of the latter type is encapsulated and hence easily enucleated, but the capsule is so thin that invasion of the adjacent tissues is frequently observed in the recurrences following removal. Although the vessels and nerves are usually simply displaced, they may be so adherent as to render separation impossible. The older teaching that regional involvement of lymph nodes is rare must be changed in view of recent experiences. As to sarcoma of the muscles, there are two distinct forms: first, an encapsulated form, the capsule, however, being so thin that local recurrence is often observed after apparently easy enucleation, and second, an infiltrating form, in which the sarcoma invades the muscle in a diffuse manner but may be limited to the particular muscle for some time. This may explain why in some cases cure has followed excision of a single muscle.

In addition to the sarcomas arising in the intermuscular septums and muscles, other types are found, such as bone-forming tumors in the muscular tissue, i. e. osteoblastic sarcomas; also sarcoma of the aponeurosis, and myxoid fibrocytomas. Pulmonary metastases are the most common, having been found in twenty-nine of the 119 cases. Microscopically, one observes various types, such as (a) the type with undifferentiated structure, eight cases; (b) the fibroblastic type, thirty-eight cases, in only five of which was the patient alive three years after operation; (c) the lipoblastic type, thirty-three cases, with only five three year cures in twenty-six cases; (d) the rhabdoblasic type, which is also very malignant, thirteen cases; (e) the osteoblastic type, which is extremely malignant, and (f) the angio-blastic type, either pure or mixed.

The prognosis in general is unfavorable; only fifteen apparent (three year) cures were observed in 119 cases. The duration of life without operation is, on an average, two or three years; hence operation is justifiable. If exploration reveals a well encapsulated tumor, it should be removed. If there is no such encapsulation, the choice lies between amputation and irradiation. The latter offers a prospect of cure if the microscopic study reveals the existence of types like the undifferentiated or embryonal tissue form, or the osteoblastic, because they are radiosensitive. If a fair trial of irradiation for these two types shows no decrease in the size of the tumor, only amputation

can be considered. For all other types surgical intervention is indicated, e. g. disarticulation at the hip or shoulder or even a more radical operation.

The discussion was opened by Mr. Gordon Taylor of London, who had collected sixty-two cases of sarcoma of the muscles, nineteen of which were personally observed. The use of radium had given disappointing results. In some cases high voltage roentgen therapy was very successful, but in spite of an occasional good result Mr. Taylor agreed with Drs. Moulouguet and Pollosson that only radical surgical measures were indicated. This was also the opinion of Professor Tixier of Lyons after a trial of all other methods of treatment. Dr. Antoine Bécère of Paris believed that it was advisable to irradiate in all cases, because, although about 30 per cent of the sarcomas are radio-sensitive, it is impossible in advance to judge which are radio-sensitive. If the tumor decreased in size after irradiation, the operative intervention could be carried out in a less radical manner and the end results would not be changed, because irradiation had been employed.

#### OTHER PAPERS

Dr. Robert Mondor made a plea for early intervention in cancer of the lung. The majority of cancers were primary in the bronchi, and the chances for a favorable result depended on an early diagnosis. Operative intervention was indicated because irradiation was of no avail. The diagnostic signs were seldom clearcut; hence bronchoscopic examination, biopsy and search for the characteristic cells in the sputum must not be delayed. A round shadow was seen as often with pulmonary echinococci as with cancer. Exploratory thoracotomy merited being employed far more frequently than it had been in the past. In two cases favorable conditions for operation existed; one patient shows no signs of recurrence two and a half years after operation, but the other died of acute pulmonary edema as a post-operative complication. As favorable conditions for operation Dr. Mondor regarded localization to one lobe, absence of adhesions, no evidence of extension to the hilus, pleura or diaphragm and absence of infection.

Dr. Pascalis of Paris warmly endorsed the plea for exploratory pleurotomy, which is not followed by any serious complications provided an artificial pneumothorax has been established as a preliminary measure.

Drs. Loubat and Magendie of Bordeaux in a paper on prevention of new bone formation after thoracoplasty recommended a 20 per cent solution of tannic acid as being far superior to solution of formaldehyde. In thirty cases they found that regeneration of bone, which is such an unwelcome complication of thoracoplasty, had usually been completely inhibited. Even when the measure was only partially successful, the new bone formation occurred so late as to play an important part.

Prof. Raymond Grégoire and Dr. Claude Bécère read a paper on uterine hemorrhages from endocrine disturbances. An abstract of a similar communication by Dr. Bécère appeared in THE JOURNAL October 22, page 1603. The authors recommended the use of hysterosalpingography in the diagnosis of chronic adnexal lesions, which are the most common source of uterine bleeding in the absence of lesions of the uterus. This method of diagnosis permits immediate exclusion of uterine causes of bleeding and early recognition of a hydrosalpinx as distinguished from salpingitis of infectious origin. The latter should be treated conservatively, but operation is indicated for hydrosalpinx.

#### Prof. Jules Bordet Honored

One of the highest honors which the French government can bestow on those who have made noteworthy contributions to the welfare of the human race was recently conferred on Prof. Jules Bordet, director of the Pasteur Institute of Brussels. This honor is a recognition of the work of Professor Bordet

in the science of immunology, which has also merited his being awarded the Nobel prize in medicine. At a recent meeting of microbiologists at the Pasteur Institute of Paris, Professor Martin, director of the institute here, conferred the insignia of the grand cross of the Legion of Honor on Professor Bordet on behalf of the French government.

#### Measurement of the Caliber of Retinal Vessels

Investigations of hypertensive and kidney disease have disclosed that for pathologic study of these disorders the condition of the arterioles, especially with respect to the width, is of significance. The only arterioles which can be observed directly are the arteries of the retina. (With their diameters of 0.1 mm. they are to be regarded as arterioles.) For evaluation of the caliber of the retinal arteries one has hitherto, *faute de mieux*, been content with a single measurement. One must consider that in myopic eyes the retinal vessels appear for optical reasons as narrower and in hyperopic eyes, on the contrary, wider. Accordingly, in taking the measurement one compares the breadth of the retinal vessels in the ophthalmoscopic picture with the diameter of the optic papilla. Attempts at more accurate mensuration have heretofore been without satisfactory results; the reason for this is that even with the maximal attention on the part of both examiner and patient the influence of minute movements could not be excluded. Therefore exact results could not be elicited by measurement with a micrometer scale, and the most accurate procedure was a measurement based on photographs of the fundus oculi.

Professor Lobeck of Jena has recently succeeded, by means of a new method, in avoiding all sources of error. If a new measuring apparatus, of his own invention, is used, only a single reading is necessary instead of the customary two readings. This device enables one in a simpler manner and in an extremely brief time (from one to two minutes) to obtain precise measurement of the caliber of vessels of the fundus oculi, and it thus creates a sound basis for conclusions relative to the pathology of kidney disease and hypertensive disorders. The new method depends on adaptation of the principle of doubling, the so-called heliometric principle, in a somewhat modified form, to the ocular of a Gullstrand ophthalmoscope of the so-called simplified type. This ocular, known as the measuring ocular, was manufactured by the Zeiss firm of Jena according to Professor Lobeck's specifications; it permits exact measurements of vascular diameter and papillary diameter to be made under identical optical conditions and thus provides good comparable values. Such results were formerly impossible, since the heliometer principle was applied not to the ocular of Gullstrand's ophthalmoscope but to the ophthalmoscopic lens which was turned toward the eye of the patient.

The new method of measuring is completely uninfluenced by any involuntary movement of the examined eye, since it is a question of only one examination. Use of this new method for measurement of the calibers of the retinal vessels and papillary border have led to the following observations: In red hypertension the values are exactly the same as in health; in pale hypertension there is an obvious contraction of the retinal arteries, and there is an even greater contraction in cases of genuine chronic interstitial nephritis. Conversely, in all three of the disorders the diameters of the retinal veins present normal values. Measurement of the caliber of the retinal arteries thus enables one to establish for the hypertensive patient a differential diagnosis of red hypertension, pale hypertension or true chronic interstitial nephritis.

In renal disorders too the retinal arteries present various measurements, whereas the venous diameters always approximate those observed in healthy subjects. In acute nephritis as

well as in nephrosis the arteries of the papillary borders are observed to be of normal width, but in chronic nephritis they are plainly contracted. Conversely, the venous diameters exhibit no narrowing. The arterial contraction is still more marked in secondary chronic interstitial nephritis but is not so pronounced as in true chronic interstitial nephritis. In retinitis albuminurica the arteries are markedly contracted if the basis is chronic interstitial nephritis and less pronounced if the basis is secondary chronic interstitial nephritis; these observations too may be of diagnostic importance.

#### Radical Operation for Mammary Cancer

Dr. O. Thies recently discussed the surgical therapy of mammary cancer in use at the surgical clinic of Tübingen University. Of greatest importance in the treatment of mammary cancer is a knowledge of the routes of metastasis into secondary tumors. It has become questionable whether the blood or the lymphatics are of the greater significance. Frequently when the cancer appears little advanced as yet according to palpation of the axillary lymph nodes, the surgeon encounters keen disappointment because of the manifestation of remote metastases following radical operation. Thies was able to determine metastases in the regional lymphatics on microscopic serial examination in 100 cases of mammary carcinoma. It was remarked how often confusion of inflammatory changes with metastases and the reverse proved a source of serious error. Frequently histologic examination of the smallest lymph nodes would disclose widespread metastases, whereas clinically prior to and at operation no metastatic sites were encountered. In follow-ups of the patients, complete correspondence was evidenced between the prognosis based on tissue studies and the further course. Not only was the importance of the lymphatics in the metastasis of carcinoma again corroborated, the value and suitability of radical operation was also established. The latter should include removal of the pectoralis minor muscle.

#### Professor von Noorden 80 Years Old

Carl von Noorden celebrated his eightieth birthday September 13. A pupil of Riegel and Gerhardt, Noorden was from 1894 to 1906 director of the internal medical section of the municipal hospital at Frankfort on the Main. He then went to Vienna to succeed Nothnagel as ordinarius in internal medicine. In 1913 he returned again to Frankfort, there to direct a private clinic. In 1929 he accepted a call from the city of Vienna to serve as consultant to the municipal hospitals on disorders of metabolism and nutrition as well as dietetics. Preeminently a clinician, von Noorden contributed to numerous domains of internal medicine, especially to the knowledge of the pathologic and clinical aspects of metabolic disorders such as diabetes, diseases of the kidney, the anemias, obesity, and intestinal disorders. He is the author of several well known monographs on these conditions. His book on diabetes, "Die Zuckerkrankheit und ihre Behandlung" (the later editions of which were written in collaboration with Isaac) and the manual for diabetic patients, "Verordnungsbuch und diätetischer Leitfaden für Zuckerkrankhe," of which Isaac was likewise co-author, are widely used and have passed through numerous editions.

#### Prof. Dr. Edgar Atzler Is Dead

Prof. Dr. Edgar Atzler, director of the Kaiser Wilhelm Institute of Occupational Physiology, Dortmund, is dead at the early age of 50. Atzler may be called the founder of present day occupational physiology. He founded the institute in 1929 after having directed a smaller similar institution in Berlin for some years. Atzler published much that was fundamental to his chosen field, including studies of the anatomy and physiology of work, the interrelation of nutrition and working capacity and the suitability of industrial apparatus. In addition he published a textbook "The Body and Work" and founded the journal *Arbeitsphysiologie*. It has already been possible to turn a good part of the results of his investigations to practical account.

#### BUDAPEST

(From Our Regular Correspondent)

Oct. 15, 1938.

#### Electrical Shock

Dr. Kormoczi, senior physician to and for thirty years in the service of the Budapest Ambulance Society, says that to resuscitate a patient following an electrical accident first aid should be given on the spot by the immediate application of artificial respiration. Professor Jellinek, lecturer on electrical accidents, protested against the belief of some physicians that a period of from five to eight minutes between the cessation of respiration and the commencement of artificial respiration is of no special importance. In Kormoczi's experience the very first minutes are most important and decisive. Artificial respiration should be applied in every instance.

#### Prof. Tiborius Györi

Medical science mourns the loss of Tiborius Györi, professor of medical history at Budapest University. Györi graduated in 1894 and Budapest University sent him to Düsseldorf, Germany, in 1898 to study the medical history exhibition there. He knew not only German but also French, Italian, Latin and Greek. He spent weeks studying the exhibits and decided there to devote his life to medical history. During the years 1898-1900 he wrote thirteen historical treatises and two large historical works. After finishing a book on Hungarian medical bibliography he undertook to answer the question: What was the epidemic disease which appeared in the sixteenth to eighteenth centuries in Hungary and spread through Vienna to Germany and the Netherlands and was then called morbus Hungaricus? He collected data from seventy-four original publications, from which he concluded that morbus Hungaricus was exanthematous typhus. His work became known to Germany and in 1898 the medicohistorical part of Virchow's Jahresbericht der gesamten Medizin was written in part by him. In 1900 Györi became lecturer to the Budapest University on medical history. He undertook to investigate the family tree of Ignatz Semmelweis, to prove that the latter was Hungarian. He gave a memorial address on Semmelweis at the Royal Medical Society's festival in 1909 and shortly afterward at the Semmelweis memorial festival of the university. It was his idea to issue a stamp to popularize the memory of Semmelweis. In 1923 he began a series of historical lectures before the medical society, for which he was awarded a prize by the society. In 1928 he was invited by the medicohistorical institute in Leipzig, Germany, to lecture. The Ministry of Public Instruction delegated him to represent the Hungarian university at foreign medical congresses in sixteen instances. In 1930 he was entrusted with writing the history of the faculty of medicine of the Peter Pazmany University, Budapest, on the occasion of its tercentenary. This is his most valuable work.

#### Marriages

PAUL H. RHODES, Albemarle, N. C., to Miss Ruth Draper of Belmont, Mass., August 13.

THOMAS VIRGIL BANKS to Miss Stella Jane Hulen, both of Hughes, Ark., in September.

JOSEPH M. CHISHOLM, Brighton, Tenn., to Miss Frances Scott of Fayetteville, Tenn., September 3.

ROBERT LATEINER, New Rochelle, N. Y., to Miss Dorothy Kasenetz of Mount Vernon, at Bedford Hills, July 6.

CECIL R. GILBERTSEN, Janesville, Wis., to Miss Dorothy Agnes Buell of Watertown, August 6.

LEO R. WEINSHIEL to Miss Ruth Padway, both of Milwaukee, August 18.

MARK TEMKIN, Beaver Dam, Wis., to Miss Pearl Ann Solomon of Racine, August 9.

## Deaths

**William Henry Seemann** \* New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1900; member of the House of Delegates of the American Medical Association, 1915-1916, 1919-1926 and 1930-1938; professor of hygiene at his alma mater and formerly professor of hygiene and tropical medicine at the New Orleans Polyclinic; at one time city bacteriologist; member of the American Society of Clinical Pathologists; at the 1938 session of the American Medical Association in San Francisco he accepted the first Distinguished Service Medal of the Association on behalf of Dr. Rudolph Matas, New Orleans, who was chosen to receive the award but was unable to be present at the meeting; aged 60; died, November 19.

**J. Norman Henry** \* Philadelphia; University of Pennsylvania Department of Medicine and Surgery, Philadelphia, 1895; member of the House of Delegates of the American Medical Association from 1926 to 1931 and in 1933; past president of the Medical Society of the State of Pennsylvania and the Philadelphia County Medical Society; director, department of public health, Philadelphia, from 1932 to 1936; formerly clinical professor of medicine, Woman's Medical College of Pennsylvania; served during the World War; consulting physician to the Pennsylvania Hospital; formerly manager of the Christ Church Hospital; at one time trustee of the University of Pennsylvania; aged 65; died, October 4.

**Frank Cary** \* Greenbush, Wis.; Rush Medical College, Chicago, 1882; member of the Illinois State Medical Society; fellow of the American College of Surgeons; served during the World War; at one time lecturer in pathology, professor of pathology and professor of internal medicine at the Woman's Medical College, Chicago; senior obstetrician to St. Luke's, Michael Reese and Lying-In hospitals, Chicago; the pavilion at the Chicago Lying-In Hospital was named in his honor; aged 80; died, September 8, of coronary insufficiency, hypostatic pneumonia and arteriosclerosis.

**John Harper Girvin** \* Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1892; associate professor of gynecology at the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; instructor in gynecology at his alma mater, 1894-1900 and demonstrator of obstetrics, 1895-1915; fellow of the American College of Surgeons; secretary of the College of Physicians, 1918-1934; served on the staff of the Presbyterian Hospital in various capacities; aged 69; died, October 23.

**Howard Anderson McCordock**, St. Louis; University of Buffalo School of Medicine, 1923; professor of pathology at the Washington University School of Medicine; formerly assistant pathologist to the Buffalo General Hospital, 1923-1924; national research fellow in medicine, Johns Hopkins University, Baltimore, 1924-1927; member of the American Association of Pathologists and Bacteriologists and the American Society for Experimental Pathology; aged 43; died, November 13, in the Barnes Hospital of aortic stenosis.

**Henry Otto Wyneken** \* San Antonio, Texas; Chicago College of Medicine and Surgery, 1912; past president and secretary of the Bexar County Medical Society; served during the World War; chairman of the board of managers of the Robert B. Green Hospital; physician in charge of the Grace Lutheran Sanatorium, 1913-1915; organizer and first president of the city association for the blind; aged 52; on the staff of the Santa Rosa Hospital, where he died, September 14, of pulmonary embolism.

**Alfred F. Van Horn** \* Plainfield, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1884; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; past president of the Union County Medical Society; for many years school physician; on the staff of the Muhlenberg Hospital; aged 77; died, September 30, of coronary thrombosis.

**Joseph Marvin Ferguson**, South Carrollton, Ky.; Kentucky University Medical Department, Louisville, 1902; member of the American Psychiatric Association; served during the World War; at one time surgeon in the U. S. Public Health Service and on the staffs of various Veterans Administration facilities; formerly county health officer; aged 60; died, September 21.

**James Joseph McGuire** \* Trenton, N. J.; University of Pennsylvania Department of Medicine and Surgery, Philadelphia, 1900; secretary of the state board of medical examiners;

fellow of the American College of Physicians; on the staffs of St. Francis Hospital and the Orthopedic Hospital; aged 62; died, October 11, of arteriosclerosis, uremia and nephritis.

**Gaston Lefebvre de Bellefeuille**, Montreal, Que., Canada; M.B., Laval University Medical Faculty, Montreal, 1903, and M.D. in 1905; Laval University Faculty of Medicine, Quebec, 1906; professor of clinical psychiatry at the University of Montreal Faculty of Medicine; member of the American Psychiatric Association; aged 56; died in September.

**Thomas Buttermore Echard**, St. Petersburg, Fla.; University of Pennsylvania Department of Medicine and Surgery, Philadelphia, 1901; member of the Florida Medical Association; formerly on the staffs of the Mound Park Hospital, St. Anthony's Hospital and the American Legion Crippled Children's Hospital; aged 60; died, September 24.

**Henry Theodor Von Deesten** \* Jersey City, N. J.; Columbia University College of Physicians and Surgeons, New York, 1901; fellow of the American College of Physicians; on the staffs of the Christ Hospital, Jersey City, St. Mary Hospital, Hoboken and Bayonne (N. J.) Hospital; aged 58; died, September 1, of angina pectoris.

**Louis Joseph Bragman** \* Binghamton, N. Y.; Syracuse University College of Medicine, 1921; member of the American Psychiatric Association; for many years affiliated with his alma mater in various teaching capacities; on the staff of the Syracuse Psychopathic Hospital; aged 40; died, October 12, in the City Hospital of pneumonia.

**Henry Alexander Sussman** \* Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1915; formerly assistant clinical professor of medicine, Long Island College of Medicine; served during the World War; on the staff of the Jewish Hospital; aged 47; died, October 16, of heart disease.

**James Ernest Daniel**, Greenville, S. C.; Medical College of the State of South Carolina, Charleston, 1905; member of the South Carolina Medical Association; served during the World War; city physician; formerly associate editor of the *Journal of the South Carolina Medical Association*; aged 55; died, September 24.

**Frank Allen Benedict**, Seymour, Conn.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1887; member of the Connecticut State Medical Society; aged 77; died, September 13, of arteriosclerosis, hypertension, cerebral thrombosis, cardiac infarction and bronchopneumonia.

**Cornelius Joseph McGillicuddy**, Boston; Harvard University Medical School, Boston, 1896; veteran of the Spanish-American and World wars; formerly connected with the U. S. Veterans Bureau; aged 67; died, September 15, in Chelsea of arteriosclerotic heart disease and cirrhosis of the liver.

**Victor Hugo Dye**, Sistersville, W. Va.; Maryland Medical College, Baltimore, 1901; member of the West Virginia State Medical Association; county coroner; aged 61; died, September 27, in the Ohio Valley General Hospital, Wheeling, of perforated gastric ulcer and peritonitis.

**Charles Vilas Martin** \* Maryville, Mo.; Hahnemann Medical College and Hospital, Chicago, 1901; at one time adjunct professor of pediatrics and clinical instructor at his alma mater; on the staff of St. Francis Hospital; aged 59; died, September 25.

**Arthur Lionel Patch** \* Windsor, Vt.; Harvard University Medical School, Boston, 1909; past president and secretary of the Windsor County Medical Society; on the staff of the Windsor Hospital; aged 58; died, September 17, of malignant hypertension.

**John Charles Lynch**, Kansas City, Mo.; Medico-Chirurgical College of Kansas City, Mo., 1905; member of the Missouri State Medical Association; veteran of the Spanish-American and World wars; aged 69; died, September 15, of coronary thrombosis.

**William Wheelock Quinlan** \* Wilmette, Ill.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1891; medical referee of the Mutual Life Insurance Company; aged 71; died, September 24, of heart disease.

**Theodore Williams Ely**, Manchester, Mass.; Western Reserve University Medical Department, Cleveland, 1909; member of the Massachusetts Medical Society; served during the World War; aged 53; died, September 25, of coronary heart disease.

**James Rodolph Taylor** \* Sidney, Neb.; University College of Medicine, Richmond, 1907; past president of the Cheyenne County Medical Society; medical superintendent of the Taylor Hospital; aged 58; died, September 1, of coronary thrombosis.

**Joseph Ezra Wells** ♂ Cynthiana, Ky.; Medical College of Ohio, Cincinnati, 1881; past president of the state board of health and the Kentucky State Medical Association; on the staff of the Harrison Memorial Hospital; aged 77; died, September 3.

**Augustus Edwin Simonton** ♂ Jonesboro, La.; College of Physicians and Surgeons, Baltimore, 1883; for many years bank president; aged 77; died, September 12, in a sanatorium at Dallas, Texas, of cerebral hemorrhage and arteriosclerosis.

**John Luther Nall**, Danville, Va.; North Carolina Medical College, Davidson, 1905; member of the Medical Society of Virginia; aged 61; on the staff of the Memorial Hospital, where he died, September 30, of myelogenous leukemia.

**Arthur Aldridge**, Richmond Heights, Mo.; University of Louisville (Ky.) Medical Department, 1872; aged 88; died, September 24, in Manchester of bronchopneumonia, uremia, chronic myocarditis, arteriosclerosis and nephritis.

**Benjamin Wallace Vitou** ♂ A. Surg., Lieut. (j. g.) U. S. Navy, Portland, Ore.; Creighton University School of Medicine, Omaha, 1936; aged 26; was drowned recently at Chefoo, China, where he was stationed aboard the U. S. S. *Ford*.

**Charles Edmund Stewart**, Palmer, Iowa; College of Physicians and Surgeons, Keokuk, 1887; member of the Iowa State Medical Society; aged 75; died, September 3, in St. Joseph Mercy Hospital, Fort Dodge, of coronary sclerosis.

**Samuel Tilden Silverman**, New York; Columbia University College of Physicians and Surgeons, New York, 1906; aged 54; died, September 8, in the Mount Sinai Hospital of carcinoma of the splenic flexure of the colon.

**James E. Gudge**, Cynthiana, Ind.; Medical College of Evansville, Ind., 1883; member of the Indiana State Medical Association; formerly bank president; aged 80; died, September 12, of heart disease and arteriosclerosis.

**John Francis Morgan**, Joplin, Mo.; Columbus Medical College, 1881; member of the Missouri State Medical Association; aged 83; died, September 2, in St. John's Hospital of cerebral thrombosis and arteriosclerosis.

**Bismarck Ferguson**, Houston, Texas; University of Texas School of Medicine, Galveston, 1903; veteran of the Spanish-American War; aged 61; died, September 22, in the Methodist Hospital of carcinoma of the stomach.

**Samuel Beatty Robb**, Leonard, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; aged 69; died, September 26, in the University Hospital, Ann Arbor, of monocytic leukemia.

**Aaron Albert York**, Empire, Ala.; Birmingham Medical College, 1906; member of the Medical Association of the State of Alabama; aged 59; died, September 24, of heart disease, hypertension and arteriosclerosis.

**Vance Lee Fitzgerald** ♂ Barrington, R. I.; Bellevue Hospital Medical College, New York, 1895; fellow of the American College of Surgeons; aged 75; died, September 24, in the Memorial Hospital, Pawtucket.

**William Thaddeus McRea**, North Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1912; aged 57; died, September 13, in the Veterans Administration Facility, North Little Rock.

**Jacob Austin Knight**, Orient, Ohio; Starling Medical College, Columbus, 1903; visiting physician at the Institution for Feeble-minded for many years; aged 66; died, September 23, of pulmonary tuberculosis.

**Carl Neu**, Seattle; Kaiser-Wilhelms-Universität Medizinische Fakultät, Strassburg, Germany, 1901; aged 64; died, September 28, of bronchopneumonia, cerebral hemorrhage and hypertensive heart disease.

**Benjamin Aiken Phillips**, Houston, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1893; veteran of the Spanish-American War; aged 71; died, September 12, of heart disease.

**James Ashley Mourfield**, Lenoir City, Tenn.; Vanderbilt University School of Medicine, Nashville, 1883; member of the Tennessee State Medical Association; aged 83; died, September 16, of heart disease.

**Vernon Tarver** ♂ Star City, Ark.; University of Arkansas School of Medicine, Little Rock, 1926; county coroner; served during the World War; aged 40; died, September 11, in a hospital at Little Rock.

**Otto L. Sahlender**, St. Louis; St. Louis Medical College, 1896; member of the Missouri State Medical Association; aged 68; died, September 8, of carcinoma of the stomach and pulmonary tuberculosis.

**William C. Weber** ♂ Cleveland Heights, Ohio; Starling Medical College, Columbus, 1888; an Affiliate Fellow of the American Medical Association; aged 79; died, September 15, of bronchopneumonia.

**Mary Gould Hood**, Boston; Woman's Medical College of Pennsylvania, Philadelphia, 1874; member of the Massachusetts Medical Society; aged 88; died, September 19, at the Waltham (Mass.) Hospital.

**Hugh McGuire** ♂ Alexandria, Va.; University College of Medicine, Richmond, 1894; on the staff of the Alexandria Hospital; aged 67; died, September 7, of cerebral thrombosis and arteriosclerosis.

**William Holmes Crowley**, Hartford, Conn.; University of Buffalo School of Medicine, 1890; on the staff of St. Francis Hospital; aged 72; died, September 12, of angina pectoris and hypertension.

**James H. Madden**, Colorado Springs, Colo.; Missouri Medical College, St. Louis, 1885; member of the Colorado State Medical Society; aged 78; died, September 26, of coronary thrombosis.

**William Meredith**, Beaverdam, Va.; Medical College of Virginia, Richmond, 1886; for many years member of the county school board; aged 73; died, September 9, of coronary occlusion.

**John Henry Mayer**, Lakeland, Fla.; Baltimore Medical College, 1902; formerly superintendent of the Chambersburg (Pa.) Hospital; aged 60; died, September 10, of cardiac decompensation.

**Wallace E. Steele**, Carthage, Mo.; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1901; aged 84; died suddenly, September 13, of chronic myocarditis and angina pectoris.

**Wendell Tracy Smith**, Pontiac, Mich.; University of Michigan Medical School, Ann Arbor, 1927; for many years county physician; aged 53; died, October 6, in St. Joseph Mercy Hospital.

**William Madison Young**, Jefferson, Iowa; College of Physicians and Surgeons, Keokuk, 1881; member of the Iowa State Medical Society; aged 81; died, September 30, of angina pectoris.

**Harry H. Smith**, Oxford, Ohio; Medical College of Ohio, Cincinnati, 1883; member of the Ohio State Medical Association; aged 76; was killed, September 9, in an automobile accident.

**Philip Carl Matthei**, Chicago; Rush Medical College, Chicago, 1902; aged 57; died, September 2, in the Augustana Hospital of carcinoma of the rectum and mesenteric thrombosis.

**Henry H. Darby**, Omaha; College of Physicians and Surgeons, Keokuk, Iowa, 1883; aged 78; died, September 11, in the Clarkson Hospital of uremia and hypertrophy of the prostate.

**George Arlington Brown**, Winnipeg, Man., Canada; Manitoba Medical College, Winnipeg, 1904; aged 63; died, September 27, in the Deer Lodge Hospital, St. James, of coronary occlusion.

**Ernest Thornton Williams**, Catawissa, Pa.; Jefferson Medical College of Philadelphia, 1905; member of the Medical Society of the State of Pennsylvania; aged 56; died, August 6.

**Jonathan Dawson Waters**, Saluda, S. C.; Medical College of Georgia, Augusta, 1888; member of the South Carolina Medical Association; aged 71; died, September 23, of nephritis.

**John Thomas Anderson**, Chadburn, N. C.; University of Pennsylvania School of Medicine, Philadelphia, 1917; died, September 8, of cerebral hemorrhage and hypertension.

**Samuel Joseph Turcotte**, Willimantic, Conn.; Middlesex College of Medicine and Surgery, Waltham, Mass., 1921; aged 53; died, September 13, in Norwich of arteriosclerosis.

**Robert Caldwell Milburn**, Muncie, Ind.; Barnes Medical College, St. Louis, 1899; aged 78; died, September 14, of bronchopneumonia, arteriosclerosis and myocarditis.

**Clinton Carl Wright** ♂ Detroit; Cleveland Homeopathic Medical College, 1900; on the staff of the Grace Hospital; aged 62; died, September 14, in the Henry Ford Hospital.

**William King Stillman Jr.**, Atlanta, Ga.; University of Tennessee College of Medicine, Memphis, 1923; aged 40; died, September 2, of acute dilatation of the heart.

**James Augustus Simpson**, Florence, Ala.; Meharry Medical College, Nashville, Tenn., 1914; aged 61; died, September 27, of cerebral hemorrhage and arteriosclerosis.

**John W. Vaughan** \* St. Louis; St. Louis College of Physicians and Surgeons, 1884; aged 81; died, September 11, in the Missouri Baptist Hospital of pneumonia.

**R. P. Bishop**, Channing, Texas (licensed in Texas, under the Act of 1907), formerly county health officer; aged 68; died, September 23, in a hospital at Amarillo.

**William Harvey Wagoner**, Peru, Ind.; Eclectic Medical Institute, Cincinnati, 1903; secretary of the school board; aged 62; died, September 25, of heart disease.

**Otto Jack Knolle** \* Fayetteville, Texas; University of Louisville (Ky.) Medical Department, 1900; aged 60; died, September 1, of chronic myocarditis.

**Hugh Brown Todd**, Houston, Texas; Marion-Sims College of Medicine, St. Louis, 1898; aged 71; died, September 15, in Garden Villa of coronary occlusion.

**Nathaniel D. Morton**, Richmond, Va.; University College of Medicine, Richmond, 1909; aged 58; died, September 10, of myocarditis and arteriosclerosis.

**Allen M. Chilcote**, Fostoria, Ohio; University of Wooster Medical Department, Cleveland, 1875; aged 87; died, September 29, of cerebral hemorrhage.

**Robert D. Guerry**, Savannah, Ga.; Hospital Medical College, Atlanta, 1911; aged 57; died, September 3, in Bluffton, S. C., of acute myocarditis.

**Albert S. Smith**, Philadelphia; Jefferson Medical College of Philadelphia, 1876; aged 84; died, August 20, of chronic myocarditis and nephritis.

**George Edward Osgood** \* St. Petersburg, Fla.; Harvard University Medical School, Boston, 1887; aged 74; died, September 21, of myocarditis.

**Charles John Aaron** \* Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1901; aged 71; died, September 4, of coronary thrombosis.

**Louis Joseph Piuze**, St. Malachie, Que., Canada; Laval University Faculty of Medicine, Quebec, 1911; mayor; aged 53; died in September.

**William R. Wycoff**, Long Beach, Calif.; Kentucky School of Medicine, Louisville, 1882; aged 78; died, August 21, of coronary thrombosis.

**Burgoyne H. Gibson**, Richmond, Ky.; Hospital College of Medicine, Louisville, 1904; aged 67; died, September 15, of cardiorenal disease.

**Richard Lee Smith**, Waco, Texas; University of Tennessee Medical Department, Nashville, 1885; aged 74; died, September 28, of uremia.

**John J. Morrow**, New Orleans; Flint Medical College of New Orleans University, 1908; aged 56; died, August 27, of diabetes mellitus.

**John Hilliard Knight**, Moose Jaw, Sask., Canada; Queen's University Faculty of Medicine, Kingston, Ont., 1880; aged 80; died, August 7.

**William A. Kendall**, Crescent, Okla.; Baltimore University School of Medicine, 1889; aged 79; died, September 19, of myocarditis.

**Hannah Steele Sparrow**, Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1887; aged 84; died, September 30.

**Edwin Jay Clark**, Denver; Hahnemann Medical College and Hospital, Chicago, 1886; aged 76; died, September 17, of gastric ulcers.

**Fred T. Jones**, Little Rock, Ark.; Meharry Medical College, Nashville, Tenn., 1905; aged 61; died, September 10, of septicemia.

**Orrin Feldor Matthews**, Urania, La.; Memphis (Tenn.) Hospital Medical College, 1906; aged 58; died, August 27, of pneumonia.

**Robert J. Gardiner**, Biggar, Sask., Canada; McGill University Faculty of Medicine, Montreal, Que., 1902; died, August 8.

**Fred Siddens**, Bowling Green, Ky.; Barnes Medical College, St. Louis, 1902; aged 57; died, September 9, of cerebral hemorrhage.

**Louis Grear**, Cincinnati; Medical College of Ohio, Cincinnati, 1895; aged 66; died, September 2, in Loveland, Ohio.

**Harry Herbert Alger**, Stirling, Ont., Canada; Trinity Medical College, Toronto, 1893; aged 71; died, September 4.

## Correspondence

### NO AMINOPYRINE IN "ANALGIA" AND "ANTABS"

*To the Editor:*—In Dr. Kracke's paper on the relation of drug therapy to neutropenic states in THE JOURNAL, October 1, he includes on page 1259 a list of preparations described as containing aminopyrine. In this list appear the names of two of our products, namely "Analgia" and "Antabs," neither of which contains aminopyrine. The product marketed under the name "Antabs" is a comparatively simple antacid tablet containing calcium and magnesium carbonates and bismuth subnitrate; the other product, "Analgia," contains acetylsalicylic acid, acetophenetidin and caffeine.

THE WILLIAM S. MERRELL COMPANY,  
E. G. GERWE, Cincinnati.

Director of Laboratories.

### ASCORBIC ACID CONTENT OF COMMERCIAL CANNED TOMATOES AND TOMATO JUICE

*To the Editor:*—A report of the Council on Foods appearing on page 650 of the February 26 issue of THE JOURNAL included a tabulation of the vitamin C content of various canned fruit juices and of sixteen brands of commercially canned tomato juice. Work done here during the past year supplements this report and also points out the variation which may be expected in different brands of commercially canned tomatoes and tomato juice and in different samples of the same brand.

TABLE 1.—Ascorbic Acid Content of Commercially Canned Tomato Juice

Brand	No. of Cans Tested*	Milligrams of Ascorbic Acid per Cubic Centimeter			
		Maximum	Minimum	Average	Standard Deviation
A	12	0.20	0.15	0.17	± 0.021
B	12	0.17	0.15	0.16	± 0.007
C	12	0.19	0.12	0.15	± 0.021
D	12	0.26	0.20	0.23	± 0.015
E	12	0.22	0.08	0.15	± 0.041
F	12	0.19	0.12	0.14	± 0.019
G	12	0.15	0.09	0.14	± 0.017
H	12	0.20	0.14	0.18	± 0.021
I	12	0.22	0.16	0.18	± 0.019
J	12	0.23	0.11	0.18	± 0.034
K	12	0.24	0.11	0.16	± 0.027

\* The contents of each can were thoroughly mixed; triplicate samples were then analyzed for ascorbic acid.

TABLE 2.—Ascorbic Acid Content of Commercially Canned Tomatoes

Brand	No. of Cans Tested*	Milligrams of Ascorbic Acid per Cubic Centimeter			
		Maximum	Minimum	Average	Standard Deviation
E	10	0.21	0.13	0.17	± 0.020
L	10	0.22	0.13	0.19	± 0.026
D	10	0.21	0.16	0.19	± 0.013
M	10	0.21	0.15	0.18	± 0.021
K	10	0.20	0.14	0.18	± 0.015
J	10	0.22	0.15	0.18	± 0.020

\* The contents of an entire can were sieved, and triplicate samples of the resultant mixture were analyzed for ascorbic acid.

The cans were purchased from retail stores in Washington, D. C., at approximately two week intervals between April and November 1937, so that tomatoes canned during the summers of 1936 and 1937 are presumably represented. All determinations of ascorbic acid were made by the indophenol titration technic of Musulin and King (*J. Biol. Chem.* **116**:409 [Nov.] 1936). The values are given in the accompanying tables. The study shows that the variation in ascorbic acid content from can to can of a single brand may be greater than the varia-

tion from brand to brand. Probably both the variety and the condition of the tomatoes contributed to these differences. A study from this laboratory on home-canned tomatoes showed that fresh tomatoes of a single variety from the same plot of ground varied from 0.11 to 0.23 mg. of ascorbic acid per cubic centimeter, depending on the condition of the tomatoes. MacLinn, Fellers and Buck (*Am. J. Hort. Sc.* 34:543, 1937) have shown that different varieties of tomatoes vary from 0.09 to 0.59 mg. of ascorbic acid per gram. In the present study the higher values of some brands, in particular brand D tomato juice, probably indicate the use of good quality tomatoes of a variety high in vitamin content.

### AMERICAN HISTORY AS TOLD BY POSTAGE STAMPS

*To the Editor:*—In the correspondence column of THE JOURNAL, September 3, is a note from Dr. Evon Walker of Ottumwa, Iowa. He cites my booklet "American History as Told by Postage Stamps" as the source of information to the effect that a doctor has appeared on an American postage stamp. Your editorial note following Dr. Walker's letter expands a bit on the life of the man in question, Manasseh Cutler. Other letters of inquiry have come, asking for more information about the medical accomplishments of the only physician to be so honored in our history. Further search of material has revealed the following information relative to his medical training (from Parker, William, and Cutler, Julia Perkins: *Life, Journals and Correspondence of Rev. Manasseh Cutler, Cincinnati, Robert Clarke & Co., 1888*):

Soon after his return from the Rhode Island expedition (September 1778), Mr. Cutler decided upon qualifying himself to practice medicine, with a view, probably, to increase his means of usefulness, and also to secure an increase of income adequate to the wants of a growing family. He provided himself with the works of a number of valuable medical authors, and commenced his studies under the direction of his friend and parishioner, Dr. Elisha Whitney. He likewise accompanied the Doctor in his daily visits to his patients, in order to study symptoms and development of disease. With a mind well disciplined to study, his progress was rapid. He comprehended almost at a glance the leading principles of the science, and in a very short period won for himself among the medical profession the reputation of a safe and skilful practitioner. . . .

On June 13, 1785, Mr. Cutler addressed the following letter to Dr. N. W. Appleton: Sir: I have received your letter inclosing an extract from the Records of the Massachusetts Medical Society, by which I am informed that the Society has been pleased to elect me an honorary Fellow. I very sensibly feel the honor conferred upon me by so learned and respectable a Society. This mark of attention is the more flattering as the Medical Art is not my profession. Please to express my acceptance and my warmest acknowledgments to the Society for the honor they have done me. . . .

This doctor-merchant-lawyer-preacher-statesman is shown on the 3 cent stamp commemorating the one hundred and fiftieth anniversary of the Northwest Territory, by reason of his organizing the project. The Northwest Territory was created by the ordinance of 1787, which made the land bounded by the Ohio and Mississippi rivers, the Great Lakes and New York an integral portion of the United States. Colonization was hastened and provisions were made for self government in the new land. So far as I have been able to determine, no other person whose face appears on a stamp of the United States was a qualified member of the medical profession.

CHARLES C. GILL, M.D., Denver.

Fitzsimons General Hospital.

## Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

### MULTIPLE BLOOD TRANSFUSIONS

*To the Editor:*—I should like to know whether there is any danger associated with giving too many transfusions over a period of a month. I had planned on giving three a week for two weeks or longer, but it seems to me that I have read somewhere that too many transfusions may do more harm than good.

M.D., North Carolina.

ANSWER.—The unquestionably great benefits of multiple blood transfusions are occasionally offset by serious or fatal accidents. These can usually be traced to technical errors. Mistakes in grouping or in labeling donors have been responsible for the majority of these tragedies, although some have resulted from other errors in technic. It is well known that a suitable donor's blood may not be compatible with the same recipient ten days later, and severe anaphylactic reactions may occur, probably as the result of iso-agglutinins or of the development of intragroup type (Culbertson, C. G., and Ratcliffe, A. W.: *Reaction Following an Intragroup Blood Transfusion, Am. J. M. Sc.* 192:471 [Oct.] 1936). When a patient requires repeated transfusions, careful cross typing must be done immediately preceding each transfusion. In spite of such care, it has been maintained by many observers that reactions are more frequent after a number of transfusions have been given. Frequently the benefits seem less after a series of transfusions, but there are so many conditioning factors to be considered, such as the progress of the underlying disease and lack of further response of the bone marrow, that this impression must be guarded. On the other hand, Clute (Hemorrhage in Obstructive Jaundice: Case Report with Recovery After Twelve Transfusions, *S. Clin. North America* 13:609-615 [June] 1933) reported a case in which twelve transfusions were given within a week and the patient's life was undoubtedly saved thereby. When large quantities are deemed necessary, Marriott and Kekwick (Continuous Drip Blood Transfusion, *Proc. Roy. Soc. Med.* 29:337-338 [Feb.] 1936) advise the use of the drip method with oxygenation of citrated blood. They have given as much as 5,620 cc. in fifty-one and a half hours, raising the content of hemoglobin from 20 to 88 per cent without untoward results. There are many cases on record in which a greater number of transfusions has been used than that contemplated by the inquirer. The benefits vary with the indications for the transfusions and the curability of the underlying disease.

### "CHROME HOLES"

*To the Editor:*—I have an industrial accident problem at one of our local factories where a good deal of chromium plating is done. The chromium bath is a solution of chromic acid. Whenever the operative has a slight defect in the skin, such as a small scratch, the acid or the acid fumes working into the skin produce an indolent ulcer. These ulcers do not heal if the operative continues at work, even if the hands are protected by rubber gloves, as the acid or the fumes seem to get in in some way. The ulcerative lesions on the hands and fingers will heal fairly well whenever the operative is taken away from this type of work, but it is difficult to do this always. Can you suggest any sort of a protective or medicated dressing which will permit healing of these small skin areas and still allow the operative to continue his work?

C. R. ABBOTT, M.D., Clinton, Mass.

ANSWER.—Unlike ordinary acids, chromic acid is not readily hydrolyzed by those chemicals making up flesh. As a result, the action of chromic acid persists indefinitely, leading to deep "chrome holes."

If the lesion or lesions are small and superficial, it may prove desirable to scrub off the damaged tissues thoroughly with 5 per cent sodium hyposulfite solution or even with water or saline solutions. The purpose of this treatment is to dislodge and remove all tissue containing chromium compounds so that additional damage may not be done by burrowing. After this scrubbing, the wound may be treated just as is any abrasion of similar severity.

If the damage already done is extensive and the chrome holes are too deep for this action, wet dressings of sodium hyposulfite should be applied for a period of from three to five days. This will result in some hastening of the reduction of the chromium compound but apparently does not lead to the dislodgment of the chromium in the flesh. Then wet dressings of

a 5 to 10 per cent solution of sodium citrate, sodium lactate or potassium and sodium tartrate should be applied for the purpose of stripping the chromium from the tissues. Such dressings may be continued for another period of three to five days, depending on the severity of the condition. After that time the treatment ordinarily may take on the character appropriate for any ulcer. Not infrequently it becomes necessary to remove the necrosed tissue in the ulcer by curettage, since this affected flesh acts as a foreign body.

In some instances the treatment may be carried out during the continuation of work, but additional exposure is undesirable and it is often preferable to remove the worker from his customary duties, at least during the early stages of treatment.

#### INTRACTABLE VESICULAR DERMATITIS

*To the Editor:*—A white woman aged 30, not employed, has minute vesicles, which first appear intracutaneously and contain a thin colorless fluid. The vesicles rupture and there is a denuded area underneath which continues to exude a colorless fluid with no crust formation. The lesions are intensely pruritic. Since the vesicles are about 2 mm. apart, there is a confluence of the denuded area. The lesions first appeared on the dorsum of both great toes in a symmetrical arrangement; they next appeared on the dorsum of the feet and tibial surface of the legs about the middle third. The next involvement was the medial side of the hands just medial to the hypothenar eminences. The involvement of the hands has included the dorsum of the first two digits of both hands. The lesions have developed over a period of eighteen months. Smears reveal no bacteria nor fungi, although intradermal tests show the patient sensitive to fungus. The patient is generally in good health, well nourished and with no gynecologic lesions. She is subject to hay fever, being sensitive to ragweed; there have been extensive attempts to desensitize her without success. Dermatologic treatment during the last year has been extensive and varied but unsuccessful. It has consisted of successive uses of salicylic acid 5 per cent in glycerin; Whitfield's ointment, one-half strength; superficial x-rays in sufficient amount; fungus extract given subcutaneously in desensitizing doses, accompanied by phenobarbital one-half grain (0.03 Gm.) twice a day; ultraviolet therapy; ammoniated mercury ointment (U. S. P. strength); oxyquinoline sulfate, 0.4 Gm., triethanolamine, 3 Gm., crude coal tar ointment; Novoxil (Squibb), a colloidal silver preparation, and resorcinol, 1 Gm. Prescriptions containing oxyquinoline have given the most benefit and were combined with sun baths to the affected areas. At present the lesions are unchecked and affect the dorsum of one foot and both hands. New vesicles are appearing on the extensor surfaces of both hands. I am unable to find systemic or nervous disorders which might be a cause and am at the end of my remedies. Can you suggest tentative diagnosis and treatment?

M.D., Ohio.

*ANSWER:*—Judging from the positive response to the intradermal test, the patient has at some time had an infection with ringworm fungus. This often results in sensitization, which is particularly likely to occur in a person with other forms of sensitization such as hers to ragweed. It is often difficult, sometimes impossible, to determine the cause of a dermatitis, though the cause of the accompanying hay fever may be easily discovered. It would be of interest to know whether her dermatitis is worse during the ragweed season.

The first principle of treatment for an acute or subacute dermatitis is to soothe it. In weeping conditions one should apply soothing and astringent wet dressings, such as solution of aluminum subacetate diluted with about sixteen parts of cool water and applied as a thin wet dressing, not covered, but free evaporation being allowed. When the dressing becomes warm, it should be wrung out of the cool solution and reapplied. This should be kept up for a half hour to an hour, then the skin dabbed dry and calamine lotion or a dusting powder applied, either of which may contain 0.5 per cent phenol and 0.25 per cent menthol. The wet dressings should be reapplied every few hours.

After this treatment has stopped the oozing, zinc paste may be used, spread thinly. One per cent phenol may be used in it. If thought necessary to remove it, oil should be used, with great care to avoid rubbing, which may start the itching again. All forms of irritation, dust, soap and water and especially rubbing and scratching, must be avoided. As improvement from this application ceases, one may use stimulation, testing it out on a small area before applying it to the whole surface. Crude coal tar or oil of cade may be added to the zinc paste in small percentage which may be increased as the improvement again stops. When an exacerbation occurs, as it no doubt will, treatment must be started at the beginning and followed out as before. If aluminum acetate is not well borne, a saturated solution of boric acid may be used instead.

Ultraviolet radiation in suberythema doses may be helpful. If roentgen rays are used again to obtain temporary relief, the special susceptibility of the blood vessels in the extremities to this agent must be kept in mind and no stimulating local application used at the same time.

Rest should be ordered and sedatives used, if necessary, to obtain it. Sedatives often seem to have a directly beneficial effect on the dermatitis; but this may be secondary to general lessening of nervous tension and of scratching. General ultraviolet exposures or intramuscular injections of the patient's own blood may have a favorable alternative effect.

#### IRON METABOLISM

*To the Editor:*—Have any experimental data been published showing the disposition of the total amount of ferrous sulfate and iron ammonium citrate ingested daily, as follows: 1. The percentage of iron required to raise the hemoglobin 1 per cent a day where the animal has a secondary anemia with a hemoglobin of less than 50 per cent? 2. The percentage of iron stored in the iron depots of the body? 3. The percentage of iron eliminated? I would appreciate references.

M.D., New York.

*ANSWER:*—It is impossible to give a short and specific answer to this question, since there are a number of variable factors involved which have not been stated.

In man the amount of ferrous sulfate or iron ammonium citrate required daily to raise the hemoglobin 1 per cent a day when the hemoglobin is under 50 per cent is not constant. That is, in some cases 0.4 Gm. (6 grains) of ferrous sulfate is sufficient; in others, two or four times as much may be required. This variation is presumably due to variations in absorption and possibly in utilization and excretion; 0.8 Gm. (12 grains) of ferrous sulfate daily or 6 Gm. (90 grains) of iron ammonium citrate daily is sufficient to give this response in the majority of instances.

The percentage of iron stored in the iron depots of the body in anemic patients is not definitely known. In a few experiments in which iron has been given parenterally, there has been a quantitative utilization of the iron to form hemoglobin. Thus it would appear that in this case little or no iron was stored.

Only a relatively small amount of the iron ingested is actually absorbed. Hence the amount of iron eliminated will vary with the iron taken into the body.

#### TRAUMATIC SYNOVITIS

*To the Editor:*—A man received a blow on the right knee from a wheel barrow while at work. The accident was not reported. Three weeks later he had a swollen right knee joint which made walking difficult. Physical examination indicated fluid in the joint and also in the prepatellar bursa. I aspirated and found the fluid to be bloody, of a dark color, and the fluid portion fairly clear; that is, it was not xanthochromic, as one might expect if the blood had been there three weeks. I banded the knee and ordered rest. The patient returned three days later with the hydrops recurrent; aspiration showed bloody fluid as found before but not so concentrated. A week later he returned and was put to bed in the hospital for a week, the fluid disappearing almost entirely. He was discharged and was no longer under my care. Now he is suing for compensation and I must give my opinion. Was the injury of three weeks' duration when I saw him first? Is there any way of answering the question from the nature of the fluid I aspirated? On taking a roentgenogram of the joint I saw several round opaque bodies near the joint surface posteriorly. He gave no history of locking symptoms at any time or of any disability of the joint. When I had emptied the patella bursa I could palpate movable bodies in or about this bursa. They did not show on the roentgenogram. I should appreciate any reference to authorities.

M.D., Wyoming.

*ANSWER:*—The nature of the fluid can be explained on the basis of a hemorrhage with a superimposed traumatic synovitis. The hemorrhage evidently stopped and the synovitis continued.

In regard to the direct question, Was the injury of three weeks' duration when the physician first saw the patient, the answer is yes.

The foreign bodies or joint mice are due to osteochondritis dissecans. If these bodies are not caught between the joint surfaces there is no locking. They may be found in any portion of the joint and in the quadriceps bursa.

The knee should be studied in three roentgen projections. If it is possible to bend the knee to 135 degrees, the central ray should be directed from behind; i. e., the so-called Holmblad-Béclère projection.

**ETHYL CHLORIDE AND NITROUS OXIDE**

To the Editor:—Please let me know regarding the relative safety of the primary induction of anesthesia in children by ethyl chloride and gas-oxygen. I have seen the former used a good deal lately and have not been favorably impressed with the patient's reaction to it, there being some cyanosis and the blood being darker than normal. However, the anesthetist tells me that where she was trained it is used in a routine manner as a primary anesthetic for children. I have understood that gas-oxygen was not used in children under 8 or 10 years of age for induction purposes. Am I correct in this assumption?

M.D., Massachusetts.

ANSWER.—Ordinarily it is considered safer to use nitrous oxide and oxygen than to use ethyl chloride for induction of anesthesia, although ethyl chloride has been used numerous times in a dental clinic in Boston. Nitrous oxide and oxygen is frequently used for induction of anesthesia in children less than 8 years of age.

**UNUNITED FRACTURES OF RADIUS AND SYRINGOMYELIA**

To the Editor:—A man aged 49, with good nutrition and circulation, presents a fracture of the midradius, ununited after five months. The complicating factor is a nervous lesion of the cord which my associates and I have taken to be a syringomyelia of Morvan's type, producing complete anesthesia of the fractured arm. Tactile sensation is lost as well as pain and temperature distinction. Although this condition is not equal bilaterally, we believe it to be more than an injury to the brachial plexus, and it is, of course, wholly unrelated to the present fracture, preceding it by at least ten years. Should surgery be resorted to? Could healing be expected following open reduction and possible bone graft?

M.D., Ontario.

ANSWER.—The probabilities are that healing of the wound would follow after reduction and the application of the bone graft. Whether the bone graft would bring about union is more doubtful. Certainly the chances would not be as favorable as in a normal arm. Whether to operate or not would depend on the use that the patient had of the arm prior to the accident. If it was of decided value in his work, it might be worth an attempt to secure union. If it was of no use, the operation would not be indicated.

**MEDIUM FOR STREPTOCOCCUS CULTURE**

To the Editor:—Can you tell me which medium would be the best to use in my office for the growth of streptococcus in the throat? I make a routine culture in all cases of acute inflammation and practically never get streptococci. I have been using Loeffler's blood serum-Difco.

M.D., Connecticut.

ANSWER.—Loeffler's blood serum is not a suitable medium for culture of streptococci from the throat. Ordinary Petri plates made with blood agar are best suited for routine culture of material from the throat for streptococci.

**APPENDECTOMY AFTER APPENDICAL ABSCESS**

To the Editor:—In what percentage of cases of appendical abscess treated by drainage only is a secondary operation for removal of the appendix necessary?

M.D., New York.

ANSWER.—The appendix should always be removed at a secondary operation. The date of the secondary operation requires some judgment. From six weeks to six months may be necessary, depending on the patient's condition.

**FIRE EXTINGUISHERS**

To the Editor:—On page 469 in the July 30, 1938, issue of THE JOURNAL you replied to a question on fire extinguishers for x-ray departments. While mention was made of carbon dioxide extinguishers, it was not clear whether or not you meant the liquid carbon dioxide type, which during use evolves a stream of carbon dioxide gas containing a cloud of particles of solid carbon dioxide without any moisture. This type of extinguisher is perfectly safe for use on electrical equipment, since it involves no water or acids. It is also perfectly safe to the user because carbon dioxide is the only gas liberated. It is supplied by Walter Kidde and Company of Bloomfield, N. J.

GEORGE H. SCHNELLER, Corona, N. Y.

**HYSTERECTOMY AND INCIDENCE OF CANCER**

To the Editor:—In THE JOURNAL, Oct. 15, 1938, page 1492, under the Query and Minor Notes heading "Hysterectomy and Incidence of Cancer," appears a quotation from von Graff as follows: "Comparing the 0.6 per cent possibility of cancer after subtotal hysterectomy with the actual frequency of 4 per cent of stump cancer, every unprejudiced observer must admit that the danger of cancerous degeneration, present at the time of operation or developed later, is more than six and a half times as great as ordinarily reckoned." The statistics given do not seem convincing, and there is no proof that there is any definite relationship between the two groups, since neither the normal incidence of cancer is given nor the percentage of operations in an average group.

HENRY G. HADLEY, M.D., Washington, D. C.

# Medical Examinations and Licensure

## COMING EXAMINATIONS

### STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, November 26, page 2036.

**NATIONAL BOARD OF MEDICAL EXAMINERS**

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, Feb. 13-15. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

**SPECIAL BOARDS**

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. Written examination, Part I, will be held in various cities of the United States and Canada, April 8. Oral examinations for all candidates, St. Louis, May 13-14. Applications must be filed not later than sixty days prior to the date of the examinations. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF INTERNAL MEDICINE: Written examinations will be held in various parts of the United States, Feb. 20. Application must be received on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: Written examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada, Feb. 4. General oral, clinical and pathological examinations for all candidates (Groups A and B) will be given in St. Louis, May 15-16. Applications must be filed not later than sixty days prior to date of examination. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh. (6).

AMERICAN BOARD OF OPHTHALMOLOGY: St. Louis, May 15. Applications must be filed before February 15. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Memphis, Tenn., Jan. 13-14. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: St. Louis, May 12-13. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: New York, April 26. Appointments must be made before Dec. 26. St. Louis, May 16. Appointments must be made before Jan. 16. Cincinnati, Nov. 14-15. Appointments must be made before July 14. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 28-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: St. Louis, May 11-14. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY: New York, Jan. 13-15. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

**Georgia June Examination**

Mr. R. C. Coleman, joint secretary, State Examining Boards, reports the written examination held by the State Board of Medical Examiners at Atlanta and Augusta, June 14-15, 1938. The examination covered ten subjects and included 100 questions. An average of 80 per cent was required to pass. Sixty-seven candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Emory University School of Medicine.....(1937)	83.1, 83.8, 86.7, 86.8, 87.1, 87.2, 87.2, 87.4, 87.6, 87.7, 87.7, 87.8, 88.2, 88.2, 88.4, 88.5, 88.7, 88.9, 89.2, 89.5, 89.7, 89.8, 90.1, 91.2, 91.4, 91.4, 92.4	(1937)	82.8,
University of Georgia School of Medicine.....(1938)	82.5, 83.3, 83.9, 84.6, 84.6, 85, 85.1, 85.3, 85.5, 85.7, 85.7, 85.8, 85.9, 86, 86.4, 86.5, 86.5, 86.7, 86.8, 86.8, 86.9, 87.1, 87.8, 87.8, 88.1, 88.2, 88.6, 88.9, 89, 89.2, 89.8	(1938)	81.8,
School of Medicine of the Division of Biological Sciences (1937)		(1937)	85.7
Tulane University of Louisiana School of Medicine....(1938)		(1938)	86.1
Jefferson Medical College of Philadelphia.....(1937)		(1937)	90.7
Vanderbilt University School of Medicine.....(1937)		(1937)	88, 91.7
University of Texas School of Medicine.....(1937)		(1937)	94.1

Seventeen physicians were licensed by reciprocity and three physicians were licensed by endorsement from June 16 through October 12. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Arkansas School of Medicine.....(1937) Tennessee		(1934)	Arkansas,
Emory University School of Medicine.....(1935)		(1935)	Mississippi
Northwestern University Medical School.....(1936)		(1936)	Oklahoma
Tulane University of Louisiana School of Medicine....(1935)		(1935)	Louisiana
Johns Hopkins University School of Medicine.....(1937)		(1937)	Maryland
Maryland Medical College.....(1906)		(1906)	S. Carolina
St. Louis University School of Medicine.....(1935)		(1935)	Missouri
Univ. of the City of New York Medical Department.....(1891)		(1891)	Virginia
Jefferson Medical College of Philadelphia.....(1932)		(1932)	New Jersey,
Medical College of the State of South Carolina.....(1933)		(1933)	S. Carolina
University of Tennessee College of Medicine.....(1936)		(1936)	Tennessee
Vanderbilt University School of Medicine.....(1898)		(1898)	Tennessee,
(1935) N. Carolina			
Baylor University College of Medicine.....(1928)		(1928)	Texas
University of Texas School of Medicine.....(1937)		(1937)	Texas

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
College of Medical Evangelists.....(1937)		(1937)	N. B. M. Ex.
Harvard University Medical School.....(1935)		(1935)	N. B. M. Ex.
Medical College of the State of South Carolina.....(1936)		(1936)	N. B. M. Ex.

## Book Notices

**The Principles and Practice of Medicine: Designed for the Use of Practitioners and Students of Medicine.** By The Late Sir William Osler, Bart., M.D., F.R.C.P. Revised by Henry A. Christian, M.D., LL.D., S.D., Hersey Professor of the Theory and Practice of Physic, Harvard University. The 9th, 10th, 11th and 12th editions of this book were revised by Thomas McCrae. Thirteenth edition. Cloth. Price, \$9. Pp. 1424, with illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1938.

The most famous of all practices of medicine is now in its thirteenth edition and under a new editorship. Previous editions appeared under the editorship of Dr. Thomas McCrae. The following note from the preface by Dr. Henry A. Christian indicates the nature of the changes that have been made:

In the First Edition Osler put much that was based upon his personal experience at bedside or at the autopsy table. In this edition I assume responsibility for all changes and additions, not credited by name to some other; what appears not so credited is based upon my own clinical and pathological experience, much of it acquired at the Peter Bent Brigham Hospital in Boston. In preparing this revision, wisely or unwisely, I have had the assistance or criticism of no one.

The book is now rearranged so that it begins with a general discussion of infections, including the pneumonias, and thereafter takes up other infections in order. Typhoid fever occupies far less space than was required when the book was first published and when typhoid was perhaps the most prevalent of all diseases affecting mankind.

It is, of course, impossible to review even a work as important as this one line by line. The task of keeping a work of such great scope abreast of the times is a difficult one. For instance, most of the data under etiology, history and incidence refer to statistics dating back to 1900 or 1903. While such statistics are historically important, they mean little to the student of 1938. In the discussion of measles there is mention of the use of convalescent serum, but nothing is said of the more recent work with material prepared from the placenta. The section on yellow fever still says that the epidemics in the United States have been in the summer and autumn months, disappearing rapidly with cold weather. This is the same statement that has appeared in earlier editions, yet the last epidemic of yellow fever appeared in the United States in Laredo in 1903. Neither is there mention of the fact that yellow fever may again threaten because of the new discoveries that have been made relative to the residual infection now being found in jungle monkeys.

Most remarkable is the statement on the prophylaxis of syphilis and on its control. This also appeared in earlier editions but is certainly not a reflection of the great activities in relationship to syphilis which prevail today. In the section on amebiasis, reference to the outbreak in Chicago in 1933 says it resulted from sewage, yet this hardly gives a picture of what actually occurred.

The book reflects repeatedly the difficulty of a complete revision of a volume of this character. Today medicine moves so rapidly that only the most serious and consistent effort can maintain the literary virtues of a great volume of this type and, at the same time, provide for that modernity of information which is necessary in any science.

**The Fight for Life.** By Paul de Kruif. Cloth. Price, \$3. Pp. 342. New York: Harcourt, Brace & Company, 1938.

Out of his numerous contributions to the *Country Gentleman*, the *Ladies Home Journal* and the newspapers, de Kruif has assembled these sketches. The series of volumes which have brought his name before the American people as the interpreter of science for the average man now includes "Microbe Hunters," "Hunger Fighters," "Seven Iron Men," "Men Against Death" and "Why Keep Them Alive?"

The present volume is largely concerned with maternal and infant welfare, the heat treatment for disease, infantile paralysis, tuberculosis and syphilis. De Kruif still writes with the fire that characterized his first book. He must, by this time, have seen the impossibility of fulfillment of many of the promises he made in his earlier articles. Once he seemed to think that with artificial pneumothorax tuberculosis could be overcome. More recently he seemed quite convinced that nasal spraying would

prevent the transmission of infantile paralysis on a large scale. He has accepted apparently in toto the concept that maternity hospitals devoted exclusively to mothers in pregnancy would answer the problem of maternal mortality. And he, like many others, seems to feel that with money it is possible to accomplish anything. Actually, of course, it is not possible. Once scientific research has established positively the cause, the method of transmission and the specific method of preventing the disease, it becomes easy to secure money to put into effect the methods that have been established, but even then apparently it is not possible to eliminate the disease entirely.

Yellow fever, once under better control than now, threatens to emerge from the jungle. New diseases, like encephalitis apparently associated with similar conditions in horses, threaten us from time to time. Even with all that we know about diphtheria, there were only a few cities in the United States which were last year without deaths from diphtheria. Money is a help, but knowledge is more important.

De Kruif favors a revolution in our social order. He thinks always of the end and does not disturb himself over the means. Certainly he is a ferment; with a little more restraint and judgment he might have been a high explosive.

**Chronic Rheumatic Diseases: Being the Fourth Annual Report of the British Committee on Chronic Rheumatic Diseases Appointed by the Royal College of Physicians.** Edited by C. W. Buckley, M.D., F.R.C.P. Number Four. Cloth. Price, \$3.25. Pp. 160, with illustrations. New York: Macmillan Company, 1938.

This is announced as the fourth and final volume of the reports issued by the British Committee on Chronic Rheumatic Disease. Arrangements, however, are being made for a new series to appear at more frequent intervals under slightly different auspices. It contains a group of papers of original and distinctive nature. The first, contributed by Davidson and Duthie, is entitled "Can the Voluntary Hospital System Solve the Problem of Rheumatic Disease?" They review some of the economic and social aspects presented by rheumatic disease in Britain and conclude that increased facilities for the care of such patients are badly needed. The volume contains a symposium of three brief papers on sciatica, a paper on rheumatic disease in the horse, and reviews of the present status of the virus problem in acute rheumatism, vaccine therapy in rheumatism, and the use of gold salts in rheumatoid arthritis. The second of the papers on gold therapy, written by Ellman and Lawrence, constitutes a rather favorable report on the results from the use of gold in selected cases of rheumatoid arthritis. Hence, as the only American contributor, has written an excellent paper on the problem of arthritis and rheumatism in the United States. This is one of the most useful of the recent books devoted to rheumatic diseases.

**Embryonic Development and Induction.** By Hans Spemann. Mrs. Hepsa Ely Stillman Memorial Lectures, Yale University. Cloth. Price, \$3. Pp. 401, with 192 illustrations. New Haven: Yale University Press; London: Oxford University Press, 1938.

The processes of early development seem especially baffling when one begins to analyze them as Professor Spemann has done. What is it that guides the orderly sequence of events with the ever increasing complexity of structure and relationship? Some have given up in despair and called in a metaphysical "entelechy" to preside over normal development and to rearrange matters as best it may when something goes wrong. Others, like Spemann, have devoted themselves to uncovering factors concerned in the process. He has not solved the riddle but he is able to report some progress and to point out flaws in theories that have been proposed. He describes many remarkable experiments, analyzing and collating them, evaluating a large body of literature. Any one with biologic interests can follow the argument, although the details will be appreciated only by the embryologists.

The development of newts and salamanders displays vertebrate embryology in diagrammatic form, and the eggs and embryos are unique in that they can be dissected and spliced together without seriously interfering with further development. Just as the adult newt can regenerate a lost limb or optic lens, so certain differentiated parts of an embryo can, when isolated, revert to an undifferentiated condition, reveal remarkable potencies and develop in an apparently purposeful manner. Since grafts can be made from one species to another it is

possible to follow the individual cells of the transplant as they differentiate because of characteristic pigments or cell sizes. A spectacular experiment of Schotte and Spemann's is the transplantation of a bit of ectoderm from a toad embryo to the head region of a newt embryo. Although this transplant would normally have become epidermis, in its new location it produces mouth "furnishings." They are however the characteristic horny plates of the herbivorous toad tadpole, not the teeth of the carnivorous newt larva. Such activation of latent capacities which would never have been expressed normally was termed "induction" by Spemann. It has long been known (Warren Lewis) that the prospective retina (optic vesicle) when transplanted may stimulate the development of a typical lens from the prospective skin. These are cases of specific effect. In other cases the stimulus of induction appears to be no more specific than a localized increase in metabolic rate. In these cases the structure produced depends on the innate capacities of the stimulated cells and the region of the body to which it is grafted. Certain parts of young embryos (prospective notochord cells *par excellence*) may induce a complete accessory embryo, built up in part of transformed host cells, in part of transplant cells. This harmonious union of cells from widely separated species often in a single organ and the orderly arrangement of organs involve an integration which corresponds to the "wholeness" of the normal embryo. Its bearing on the origin of double monsters and teratomas is obvious but is not discussed. Spemann suggests that this "wholeness" is comparable to the psychic integration which underlies our own individuality. This assumes a mechanism of heredity as complexly organized as the human brain. He is more impressed with the part played by the innate inherited structure of embryonic cells than that which metabolic gradients or the like may play in development. Localized centers of high metabolic rate have been demonstrated in eggs and embryos (Child and others) and no evidence is presented that makes untenable the theory that gradients are the integrating factor in development.

The material is admirably presented and the English is good. In these days of supernaturalism in Europe it is most gratifying to see not only meticulous care in the assigning of credit to others but often a gracious appreciation of achievement.

**Parasitology, with Special Reference to Man and Domesticated Animals.** By Robert Hegner, Ph.D., Professor of Protozoology, The Johns Hopkins University, Francis M. Root, Ph.D., Donald L. Augustine, Sc.D., Assistant Professor of Helminthology, Harvard University, and Clay G. Huff, Sc.D., Associate Professor of Parasitology, University of Chicago. The Century Biological Series, Robert Hegner, Editor. Second edition of "Animal Parasitology." Cloth. Price, \$7. Pp. 812, with 308 illustrations. New York & London: D. Appleton-Century Company Incorporated, 1938.

This is a second revised edition of *Animal Parasitology* (1929) under a different title to remove the impression that the book was devoted primarily to the parasites of animals other than man rather than primarily to those of man and his domesticated animals. The same authors are retained with the addition of Professor Huff to supplement the work of the late Prof. Francis M. Root on Arthropods of Parasitological Importance. Professor Hegner writes the introduction on parasitism and the protozoology, Professor Augustine the helminthology. The entire text and the bibliographies have been brought down to date and new illustrations added. The book meets the needs of physicians, veterinarians, and teachers and students of human and veterinary parasitology.

**La syphilis du système nerveux: Pathologie générale, thérapeutique et prophylaxie.** Par A. Sézary, professeur agrégé à la Faculté de médecine de Paris. Paper. Price, 48 francs. Pp. 287, with 28 illustrations. Paris: Masson & Cie, 1938.

This is written in simple and concise language and is mainly the result of the author's rich experience in the past thirty years. It is divided into five parts. The first part discusses spinal fluid examinations and syphilitic meningitis. The second part discusses possible etiologic factors such as neurotropic virus, environment and the role of treatment in late nervous complications. The third part concerns itself with pathogenesis of the two great classes of nervous disorders, mainly vascular and parenchymatous nervous syphilis, and is well treated. The fourth part deals with treatment and includes drugs, treatments of specific entities and complications. The fifth part deals with

prophylaxis of syphilis of the nervous system. The laboratory examinations receive adequate discussion. Illustrations are easy to understand, being semidiagrammatic. In the treatment the value of neoarsphenamine and bismuth compounds is generally recognized, especially in the prophylaxis of nervous syphilis. In the specific treatment of dementia paralytica, acetarsone alone has been used quite extensively and the author feels it has given as good results as malaria therapy. Tryparsamide is mentioned but not discussed. The methods of malaria therapy and other means of fever therapy such as typhoid, foreign protein and electrohyperpyrexia are not discussed. Although the book does not cover the various treatments of central nervous system syphilis it is a valuable addition to the practitioner's library.

**Bile: Its Toxicity and Relation to Disease.** By O. H. Horrall, M.D., Ph.D., F.A.C.S., Department of Physiology, the University of Chicago. Cloth. Price, \$4. Pp. 434. Chicago: University of Chicago Press, 1938.

This monograph endeavors to summarize and analyze the physiologic and toxic actions of bile as revealed by "past observations and experiments." The author has made an exhaustive study of the literature dealing with the history of bile and a study of its constituents, toxicity and effect on various parenchymatous organs of the body. Three chapters are given to a study of bile and its relation to icterus. A bibliography of 2,177 references forms a valuable part of the book; in the preface it is stated that, because "it is intended to conserve the time and labor of workers in this field, only the more significant publications have been included." The book is comprehensive and should be of great interest to all workers in the field of hepatic diseases and disturbances, both clinical and experimental.

**The Big House of Mystery: A Physician-Psychiatrist Looks at Ten Thousand Crimes and Criminals.** By Patrick H. Weeks, M.D., Physician and Psychiatrist, Indiana State Prison. Cloth. Price, \$2. Pp. 259, with 5 illustrations. Philadelphia: Dorrance & Company, 1938.

The author is physician and psychiatrist to the Indiana State Prison. He presents his work not as a scientific treatise on crime but as a record of the way in which modern criminology handles the criminal. He tells his story as a series of records of notorious criminals with whom he has been in contact. Obviously the most important of them was Dillinger.

**Papers on Psycho-Analysis.** By Ernest Jones, M.D., M.R.C.P., President of the International Psycho-Analytical Association and of the British Psycho-Analytical Society. Fourth edition. Cloth. Price, \$8. Pp. 643. Baltimore: William Wood & Company, 1938.

This is the fourth edition of the collection of the Jones essays. In the present edition the author has omitted twenty old papers and inserted twelve new ones. Once this work was well nigh a presentation of all the freudian concepts. Today many of the freudian school have minor disagreements with the freudian concepts and have some new ideas of their own which have not proved acceptable to Professor Freud himself. These are also reflected in Dr. Jones's book. His ability to present his material in easily readable language and his sincere earnestness in relationship to the subject make him a leader in his field and well worthy the attention of the average physician.

**Zum Krebsproblem und verwandten Gebieten: Infektion, Regeneration, Zellmutation, Befruchtung.** Von Dr. Fritz Niedermayer, Chefarzt und Leiter der Chirurgischen Abteilung des Krankenhauses Passau. Paper. Price, 5 marks. Pp. 166. Leipzig & Vienna: Franz Deuticke, 1938.

Cancer is produced by "bastard" cells that result from the union of epithelial and connective tissue cells, or their chromosomes, with cells of the reticulo-endothelial system. Other views of the origin of cancer are considered, as are also its relation to biocatalysis, phagocytosis and infection, including virus diseases. In the author's experience malaria and exophthalmic goiter hinder the development of cancer, owing he believes to the circumstance that in these diseases there is an increased lymphocytic activity which is held to be the most important anticancer influence in the body. A report on the effect of inoculating exophthalmic tissue into cancer will be published later. While the first essential in the treatment of cancer is early diagnosis and prompt removal or destruction of the cancerous growth, measures to promote harmonic and catalytic

processes are advisable in all stages of the disease. For this purpose are recommended organ extracts, notably of the spleen and the embryonal liver, copper, arsenic, terpenes and intestinal disinfectants, but no definite courses of treatment are prescribed and no clinical results are detailed. The discussion is speculative and inconclusive. The author published a book in 1936 on the cancer problem, to which he refers frequently in this volume.

**Aids to Bacteriology.** By William Partridge, F.I.C. Sixth edition revised by H. W. Scott-Wilson, B.Sc., B.M., B.Ch., Director of the Laboratories of Pathology and Public Health, London. Cloth. Price, \$1.50. Pp. 300. Baltimore: William Wood & Company, 1938.

Since the last edition the original author, William Partridge, has died. The sections concerning streptococci, the coli-typhoid groups, Neisseria and the filtrable viruses have been revised. This little pocket edition should be quite useful to workers in the diagnostic laboratories.

## Bureau of Legal Medicine and Legislation

### MEDICOLEGAL ABSTRACTS

**Hair Dyes: Dermatitis Attributed to Use of Dye.**—The plaintiff, the owner and operator of a beauty parlor, purchased a hair dye known as Roux Shampoo Tint from an agent of the defendant, the Roux Distributing Company, a distributor for the manufacturer, the Roux Laboratories, Inc. Following the use of the hair dye on a customer, the plaintiff developed a dermatitis of her face, hands and arms. The skin over the areas involved was raised and swollen. She suffered such severe pain that she was unable to carry on her business or even do her household work. She sued the defendant, alleging that the dermatitis was due to a poisonous substance in the hair dye. The trial court rendered a judgment in her favor, the court of appeals, Cuyahoga County, Ohio, reversed that judgment and the record was certified to the Supreme Court of Ohio for review.

The buyer of a product, said the Supreme Court, not only has a contractual right that the product will be as warranted and will be fit for the particular purpose intended but the further common-law right not to be harmed or injured by some unknown or hidden ingredient or defect when the product is used in the manner intended. If the product sold is unfit for the use intended, there has been a breach of warranty, express or implied. If the buyer is injured because of some unknown dangerous ingredient in the product purchased, then there has been negligence. Circumstances may be such that both a breach of warranty and negligence exists. In the instant case the evidence showed that the hair dye was not only unfit for the purpose intended but also contained a poisonous ingredient, unknown to the plaintiff, which in the use of the product on a customer injured the plaintiff. There was undisputed medical testimony that the dermatitis had been caused, not by a "supersensitivity," but by a poison in the preparation. The plaintiff was entitled to introduce evidence tending to prove either breach of implied warranty or negligence and the trial court did not err in submitting the case to the jury on the issue of negligence.

No error was committed by the trial court in permitting a chemist to perform a "so-called experiment" while testifying. The witness, who had had many years of experience as a chemist, in order to illustrate the action of hydrogen peroxide, placed his finger in a high concentrate solution of hydrogen peroxide (100 volume), removed it from the solution and showed the jury how it was whitened and then placed his finger in a glass of water. This testimony was admitted in connection with other evidence of the chemist with respect to the effect of the hair dye in question on the human skin. There was no claim made that the witness was not a qualified chemist.

The Supreme Court reversed the judgment of the court of appeals and affirmed the judgment of the trial court in favor of the plaintiff.—*Sicard v. Kremer (Ohio)*, 13 N. E. (2d) 250.

**Workmen's Compensation Acts: Action at Law Not Maintainable for Disease Not Compensable Under Act.**—Murphy, in using a spray gun for painting in the course of his employment with the American Enka Corporation, inhaled fumes of turpentine and other chemical elements in the paint. Eventually an abscessed kidney developed, which permanently and totally disabled him. He was denied compensation under the workmen's compensation act of North Carolina, the industrial commission finding that his disability resulted neither from an injury by accident in the course of his employment nor from any of the occupational diseases made compensable by the act. The superior court, Buncombe County, affirmed the judgment of the commission, and the workman did not appeal further. Instead he instituted a common law action for damages against the employer and one of its foremen. The trial court, in effect, dismissed the action, and the plaintiff appealed to the Supreme Court of North Carolina.

The plaintiff and the defendant employer, said the Supreme Court, having accepted the North Carolina workmen's compensation act, are bound by its provisions. The act originally defined "injury" and "personal injury" for which compensation is allowable to "mean only injury by accident arising out of and in the course of the employment, and shall not include a disease in any form, except where it results naturally and unavoidably from the accident." Thereafter the legislature in 1935 extended the provisions of the act to cover named occupational diseases. The workman conceded that the injury of which he complained was not an occupational disease named in the 1935 amendment. He contended, however, that the statutory definition of the word "accident" eliminated his injury from the provisions of the compensation act and that a common law action against his employer would lie for actionable negligence. With this contention the Supreme Court disagreed, citing *Lee v. American Enka Corp.*, 212 N. C. 455, 193 S. E. 809, in which it was said:

When the plaintiff in this action failed to reject the North Carolina Workmen's Compensation Act, as applicable to his employment by the defendant, American Enka Corporation, and thereby became subject to its provisions, in consideration of the liability assumed by the said defendant to pay to him compensation for an injury which he might suffer by an accident arising out of and in the course of the employment, without regard to whether the accident and resulting injury were caused by its negligence, he surrendered his right to recover of the defendant damages for an injury caused by the negligence of his employer, and waived his right to maintain an action in the superior courts of this state to recover such damages.

For the reasons stated the judgment of the trial court dismissing the action was affirmed.—*Murphy v. American Enka Corporation (N. C.)*, 195 S. E. 536.

**Accident Insurance: Arrested Arthritis Not a Disease.**—The defendant insurance company issued a policy on the life of Upchurch providing double indemnity if death resulted "directly, and independently of all other causes, from bodily injury . . . effected directly through external, violent, and purely accidental means . . . and not caused by or contributed to, directly or indirectly, or wholly or partially, by any disease." In 1934 Upchurch had arthritis in his left ankle and left knee, which lasted four or five days. Thereafter he seems to have completely recovered; he was not sick, he lost no time from his work as a traveling salesman and he indulged in physical exercise such as cultivating a garden. Dec. 1, 1936, he fell down a flight of steps and injured his left knee and left ankle. He was able to get about for several days but pains developed in both legs and in his back. His attending physician diagnosed his ailment as acute arthritis. On December 23 he died. The insurance company denied liability under the double indemnity clause and Upchurch's beneficiary, his widow, brought suit against the company. The jury returned a verdict in her favor and when the trial court refused to order a new trial the insurance company appealed to the court of appeals of Georgia, division 2.

The sole question before the court of appeals was whether the evidence was sufficient to justify the jury in finding that the death resulted proximately from a bodily injury of the character described in the double indemnity clause and not from

a disease. Medical witnesses testified that the arthritis from which the insured died developed from germs of the disease which were in his system prior to his injury, that the germs of arthritis could be encapsulated in a person's body, or be dormant, and the person would not suffer from the disease, and that the physical injuries which the insured received from the fall caused the encapsulated or dormant germs of arthritis which were in his system to flare up and develop the disease. This evidence, in the opinion of the court, was sufficient to justify a finding by the jury that the insured did not have arthritis or any other disease prior to the fall, and that the arthritis which developed after the fall was directly caused by the injury.

The judgment in favor of the widow was affirmed.—*National Life & Accident Ins. Co. v. Upchurch (Ga.)*, 195 S. E. 588.

## Society Proceedings

### COMING MEETINGS

American Academy of Orthopedic Surgeons, Memphis, Tenn., Jan. 15-19. Dr. Carl E. Badgley, 1313 East Ann St., Ann Arbor, Mich., Secretary.  
American Association for the Study of Neoplastic Diseases, Baltimore, Dec. 28-30. Dr. Eugene R. Whitmore, 2139 Wyoming Avenue N.W., Washington, D. C., Secretary.  
American Student Health Association, New York, Dec. 29-30. Dr. Ruth E. Boynton, Students Health Service, University of Minnesota, Minneapolis, Secretary.  
Eastern Section, American Laryngological, Rhinological and Otolological Society, Boston, Jan. 11. Dr. Frank E. Kittredge, Masonic Temple, Nashua, N. H., Chairman.  
Middle Section, American Laryngological, Rhinological and Otolological Society, Sioux City, Iowa, Jan. 19-20. T. R. Gittins, Davidson Bldg., Sioux City, Iowa, Chairman.  
Southern Section, American Laryngological, Rhinological and Otolological Society, New Orleans, Jan. 14. Dr. Francis E. LeJeune, Maison Blanche, New Orleans, Chairman.  
Southern Surgical Association, White Sulphur Springs, W. Va., Dec. 6-8. Dr. Alton Ochsner, 1430 Tulane Ave., New Orleans, Secretary.

### THE AMERICAN RHEUMATISM ASSOCIATION

*Fifth Annual Meeting and Seventh Conference on Rheumatic Diseases, held in San Francisco, June 13, 1938*

LORING T. SWAIM, M.D., Boston, Secretary

(Concluded from page 2044)

#### Neurologic Symptoms and Clinical Observations in Patients with Cervical Degenerative Arthritis

DRS. STACY R. METTIER and CHARLES S. CAPP, San Francisco: The present study was undertaken to analyze the symptoms suggestive of cervical nerve root origin occurring in patients presumably having osteo-arthritis, and to attempt to correlate these symptoms with roentgenograms of the cervical vertebrae taken in the anteroposterior, lateral and oblique projections. The series consisted of thirty patients. Most of the patients were between 40 and 60 years of age. Three were under 40 years of age.

The symptoms complained of most frequently were pain, rigidity of the neck and muscular weakness of the hand or arm. In their general character and distribution the symptoms were uniform enough to lead one to suspect the presence of a common underlying pathologic process. Such, however, was not the case in our experience. Hypertrophic changes were observed in eighteen cases. These consisted of circumferential osteophyte formation which projected into the intervertebral canals. These were well visualized in the films taken in the oblique projections. In addition, in the involved regions there was slight narrowing to almost complete obliteration of the intervertebral spaces. The sites of predilection were between the fifth and sixth and the sixth and seventh cervical vertebrae. In seven cases there were similar symptoms but the roentgenograms showed only a minimal amount of osteo-arthritis. Narrowing of the intervertebral disks occurred in only three cases. In four cases presenting symptoms of radiculitis there was no apparent abnormality of the articular facets in the roentgenograms, no evidence of proliferative new bone formation at the margins of the vertebrae,

no noticeable narrowing of the intervertebral foramina and no thinning of the intervertebral disks.

This syndrome of pain and muscular stiffness about the neck and in the shoulder girdle or the radiation of pain down the arm is of relatively frequent occurrence in persons beyond 40 years of age. From our studies it was learned that in approximately two thirds of the cases there was roentgenologic evidence of hypertrophic arthritis. In the remaining cases there was no evidence of arthritis or of any other pathologic process in the x-ray films. The value of taking x-ray films in the oblique projection is emphasized. The patients were greatly relieved of their symptoms by the application of heat, massage, manual traction and manipulation, and posture training.

### DISCUSSION

DR. NEVILLE T. USSHER, Santa Barbara, Calif.: The authors ask us as internists to make a diagnosis in a field ordinarily relegated to the orthopedic department. The radicular syndrome for some time has been stressed chiefly by orthopedists and neglected by those who look for visceral pathologic conditions to account for referred external pain. In my experience degenerative changes in the cervical spine are but one factor in the production of referred pain to the occiput, shoulder girdle and precordium. Often a cervical lordosis or a scoliosis with angulation at the seventh cervical vertebra is enough to produce severe referred symptoms quite distant from the actual point of irritation. Actually these curvatures are often the prime etiologic factors in producing the degenerative changes in the vertebra. Orthopedists stress the importance of the wear and tear on the articular surfaces in producing such arthritides, and it is the malposition of weight-bearing surfaces due to these curvatures of the spine that increase this wear and tear element. The effect of cervical pathologic changes on the autonomic nervous system is important and yet insufficiently recognized. Recently in Santa Barbara I have demonstrated in a number of cases the relation of severe "sphenopalatine pain" (as described by Sluder) to disturbances in the cervical spine. Correction of angulations in this area by postural exercises or by heel raises for example have resulted in striking relief of symptoms. This "deep facial" pain is definitely associated with the sympathetic network and I feel that it cannot be explained on the basis of damage to the cervical somatic nervous system. The cervical somatics can and do take part in hyperesthesia and pain of the scalp and external facial structures but apparently do not influence typical sphenopalatine pain. My observations suggest that damage to the cervical spine and surrounding tissues over a long period may result in trophic changes of the mucous membranes of the nose and possibly may affect intra-ocular tension or muscle balance. Whether tinnitus and lessened acuity of hearing due to sympathetic irritation of the auditory apparatus is another feature I am not able to state definitely. At any rate further study of these observations is indicated. It is evident then that degenerative as well as other structural changes in the cervical spine have more effect on the body economy than has been ordinarily realized.

DR. LEWIS GUNTHER, Los Angeles: In 1893 a Russian by the name of van Bechterew published, in German, a description of the arthritic changes in the spine now known by his name and described the associated radicular muscle atrophies and sensory disturbances. Until 1928, when the description of radiculitis associated with hypertrophic osteo-arthritis of the spine by Dr. Kerr and myself appeared, the term radiculitis had been used with only a few exceptions to describe the acute sensory (and sometimes motor) disturbances such as Dejerine described in relation to syphilis of the nerve roots. The few references to the subject were by Camus in 1907, Leri in 1916, Sicard in 1918, Rosenheck in 1924 and Nielson in 1927. None of the articles, until our descriptions in 1927 and 1928, had a composite picture of the syndrome sufficient for an accurate differential diagnosis. The sufferer from arthritis of the spine has symptoms which are both objective and subjective. The subjective symptoms of radicular sensory disturbances are as accurate and of as much diagnostic importance as are the objective observations. The former can be obtained accurately during the history taking but the latter are sometimes difficult to demonstrate.

Because of the rarity of references to the neurologic complications it was our problem to prove that hypertrophic osteoarthritis of the spine could cause pain and that this pain was a variety of radiculitis. It is interesting to have heard Drs. Mettier and Capps say "we can look at the x-ray film and predict where the patient has his pain." In those days Dr. Kerr and I studied the patient's symptoms and sensory alterations and tried to predict which vertebrae would show the pathologic changes. We were able to show that there were subjective and objective sensory disturbances. These had the well defined anatomic pattern of the radicular or segmental distribution of the dermatomes of the body. We were able to demonstrate either increased or decreased sensation to the pinpoint, to the cotton tuft and to pinching the skin. Always these disturbances showed the segmental distribution. Hyperesthesia was usual when the symptoms were of recent onset. In the older patients hypo-esthesia was present throughout the entire root distribution, either unilateral or bilateral. Muscle spasms were also observed in the acute phases and muscle atrophies in the patients with symptoms of long standing. The motor disturbances were likewise of a nerve root pattern, involving muscles or groups of muscles supplied by the particular spinal nerve root or roots. In old arthritis of the lowermost cervical vertebrae we found atrophy of the thenar or hypothenar eminences. The subjective symptoms consisted of pain, aching and paresthesias, described accurately by the patient in a half or full segment covering one or more nerve root distributions. The paresthesias described as burning, numbness or tingling were of particular significance in the differential diagnosis. Paresthesias were common symptoms of root pain and were uncommon in the symptoms of visceral pain referred by way of the same nerve roots. So accurate are the topographic descriptions of the patient during the acute phases of his symptoms that one might think he had read a textbook on neuro-anatomy.

In my experience there is absolutely no quantitative relation between the amount of x-ray evidence of bony changes to the degree of symptoms. The first descriptions of radiculitis by Dejerine's pupils was of an acute process of syphilitic origin in which there were no bony changes. Herpes zoster, another manifestation of a true subjective as well as objective radiculitis, may have no relation to vertebral pathologic conditions. One might see tremendous evidence of bony involvement by means of the x-rays and witness no subjective symptoms. It is often difficult to differentiate clearly the origin of pain in the epigastrium, in the right lower quadrant, across the lower abdomen, or across the shoulders and down the outer sides of the arm and forearm. However, if the complete segmental distribution of pain of radicular origin is kept in mind, in contradistinction to the spotty zones (Head zones) occurring within parts of segments seen in visceral referred pain, the origin of any painful symptoms will be explained. Many pathologic processes in the spine may cause nerve root symptoms. Whether it is bony excrescences protruding into and decreasing the size of the intervertebral foramina, as Drs. Mettier and Capp have pointed out, or exudate as shown by Nathan in his experiments, or hypertrophic granulations, or scoliosis as pointed out by Dr. Ussher's discussion, tumors of the vertebrae or the meninges, tuberculosis or syphilis of the nerve roots as originally shown by Dejerine and his pupils, or involvement of the roots at the rib articulations as shown by Dr. Kerr, the symptoms at the periphery will be of one topographic distribution, namely segmental according to the dermatomes of the body.

The second cervical nerve root covers the scalp area from the occiput to the vertex and extends downward over a small area in front of the ear and over the posterior portion of the mandible. Most of the ear is supplied by the cranial nerves. The fourth cervical nerve root supplies the entire area of the shoulder from the second interspace in front to the spine of the scapulae behind and laterally to the surface markings of the deltoid muscle. There are two areas in this region which are not supplied by this root: The area between the surface markings of the sternomastoid muscles on the sides and front of the neck is supplied by the third cervical nerve root and the triangular area up and down the back of the neck, which has its apex at the occiput in the midline and its base approximately

at the level of the spines of the scapulae and delineated laterally by the surface markings of the deltoid muscles. This triangular area is supplied by the fifth, sixth, seventh and eighth cervical (and sometimes by the first dorsal) nerve roots. In addition to the triangular area over the back of the neck, the fifth to eighth cervical nerve roots also distribute down the outer side of the arm and forearm and to the fingers. The fifth cervical nerve root supplies the outer half of the arm from the area of the deltoid muscle to the external condyle of the humerus. The sixth cervical nerve root supplies the outer or radial half of the forearm including the thumb and first two fingers. The seventh cervical nerve root supplies part of the second and third fingers. The eighth cervical nerve root supplies the fourth and fifth fingers and the ulnar half of the forearm to approximately the inner condyle of the humerus. Here the eighth cervical nerve root lies adjacent to the first dorsal nerve root, which supplies the lower and inner half of the arm, the second dorsal root, supplying the upper half, and the third dorsal nerve root the armpit area. I wish to call attention particularly to the deltoid to thumb distribution of the upper extremity, which is supplied by the fourth, fifth, sixth and seventh cervical nerve roots in contrast to the armpit to little finger distribution, which is supplied by the third, second and first dorsal nerve roots. It is these two areas that come into consideration in the differential diagnosis of referred pain from the heart. Either area can be painful from arthritis of the cervical spine and upper dorsal vertebrae, but angina pectoris, or pain referred from the heart, confines its distribution from the armpit to the little finger area, and rarely from the deltoid to the thumb distribution of these dermatomes. Pain of nerve root origin involves the entire distribution of the dermatomes at least unilaterally, whereas referred heart pain occurs in areas within several of the nerve root distributions, covering or overlapping parts of two or more dermatomes without completely covering the entire distribution of the particular roots. Similarly, arthritis of the third and fourth cervical vertebrae will involve the entire distribution of the shoulder area and the side of the neck, whereas pain referred from the heart occupies only small areas (Head zones) within the entire dermatome.

The diagnostic picture presented is not difficult to obtain if a little effort is expended in obtaining an exact understanding of the language used by the patient. The borders of the dermatome will be accurately shown if you ask him to indicate how far down the pain reaches on the front and back of the chest and on the sides of his shoulder. In a similar way, when the fifth, sixth, seventh or eighth nerve roots are involved, radiation to the dermatomes on the outer sides of the extremities will be indicated as well as the area up and down the back of the neck. He will differentiate accurately the difference between the deltoid to thumb areas of cervical vertebrae disorder as against the armpit to little finger radiation seen in involvement of the upper dorsal vertebrae. By his descriptions he will also differentiate between the spotty (Head zone) distribution of referred heart pain and the complete area of the dermatome seen in radicular pain.

When the patient is questioned carefully on the sequence of symptoms in relation to activity, the following type of story is apt to be heard: Symptoms begin in the morning when the patient gets out of bed. He usually eases himself over the side because it is painful to sit up abruptly or to jump out of bed. The extremities feel stiff, and the hands and fingers are apt to be stiff or feel swollen. Usually by the time the morning ablutions are completed there is less pain, but shortly after the breakfast hour, when the day's physical activities have begun, symptoms return. Straining at the stool, yawning, sneezing or coughing will induce symptoms. The housewife may be annoyed sufficiently to find it necessary to lie down. She gets some relief, but her pain returns soon after she has relaxed and forces her into activity again because she gets relief by moving around. But after a while fatigue and pain return. That is the painful program of the day. If she uses her car a bumpy road aggravates her pain, or if she "misses a step" it brings on acute symptoms. At bridge or in the theater she shifts her position frequently. By bedtime the patient is thoroughly worn out, irritable and full of annoying aches and pains which have hardly ceased during the entire day. But the pain does not leave her

and she soon awakens. Shifting her position in bed affords some relief but an uninterrupted night's sleep is unknown to her. However, considerable comfort at night can be had by placing boards under the mattress or by the use of an ordinary pad mattress and a simple wire mesh support which is relatively nonyielding and gives support to the vertebral column muscles during sleep. The patient not infrequently takes the mattress from the bed and places it on the floor and there finds sufficient comfort for a peaceful night. This is the picture of the sufferer from hypertrophic osteo-arthritis of the spine.

DR. M. J. SHAPIRO, Minneapolis: Roentgenograms of a group of patients between the ages of 40 and 60 complaining of pain in the back of the neck will reveal a good many with evidence of osteo-arthritis in the spine. Before one makes a diagnosis of radiculitis it is most important to understand that many normal persons have osteo-arthritic changes in the cervical spine. It is not nearly as difficult to make this diagnosis if the dorsal spine is involved. I should like also to ask the authors whether they don't find this syndrome much more common in women—especially during the menopausal period—and whether or not this condition is not a self-limited disease. I have seen a number of patients with radiculitis and a lot of pain and after a number of months or years the whole thing disappears. Why is it that so many persons with extensive osteo-arthritis of the spine have no symptoms of radiculitis?

DR. K. K. SHERWOOD, Seattle: There is one point that has not been emphasized in these discussions about radiculitis and that is the physical examination of the patient. Frequently the differential diagnosis lies between visceral disease, intrinsic nerve disease and external pressure on the nerve. If the disease is due to pressure on the nerve where it emerges from the spinal canal, decreasing the size of that opening should increase the symptoms. This can be done simply by lateral flexion of the neck. Thus if that motion increases the pain one can say that the pain is due to pressure which is exaggerated by decreasing the size of the foramina. On the other hand, in the intrinsic nerve diseases lateral flexion will relieve the pain, whereas extending the lateral flexing of the neck from the opposite direction will increase the pain. I found this to be of value in the diagnosing of this radicular syndrome. Further, I believe that the importance of the x-rays is more in prognosis than in diagnosis.

DR. CHARLES S. CAPP, San Francisco: We purposely eliminated those cases in which there was any scoliosis or patients with extreme cervical lordosis, who project their neck far forward because of their myopia in the attempt to see better. We examined many more than forty cases, but we are trying to group those which had no other demonstrable pathologic lesions. With regard to myositis as a possible cause of pain, in some of our cases, but not in all, blood sedimentation studies were made, and in none of them did we find evidence of inflammation as indicated by increased sedimentation rate. I cannot eliminate fibrositis as a possible cause of symptoms, for we haven't taken biopsy specimens of the connective tissue or muscle. Women had symptoms in the ratio of 60 to 40 per cent to men. Frequently relief could be given women by proper support of pendulous breasts, by correcting posture or by proper use of the muscles comprising the shoulder girdle. By fluoroscopy one can determine the amount of movement of the cervical spine. If there is a narrowing of only one intervertebral disk there is no limitation of motion of the spine in flexion or extension except at the disk in question. There is definite limitation of motion if two or more disks are narrowed. Flexion narrows the intervertebral canal aperture and extension opens it. The x-ray demonstration of bone proliferation at the intervertebral disk margin is a late manifestation of the disease process. We are trying in our pathologic studies on autopsy material to correlate the presence of roentgen observations with previous clinical symptoms and to follow the progression of the disease process by clinical and x-ray studies on ambulant patients at stated time intervals.

DR. WILLIAM J. KERR, San Francisco: I have been much interested in one particular group of patients who have a pain in the cervical region, particularly those who are obese, with a large and pendulous abdomen, who lean backward to keep from

falling over. They stoop as if they were going into a tunnel. Many of these patients complain of pain in the back of the neck radiating to the side, to the occipital region or, sometimes, to the shoulders until relieved by postural correction or by dietary measures. In the ordinary relaxed position they have pain; if the abdomen is supported or if they stand erect the pain is immediately relieved. I don't know the mechanism of relief unless it is the change in the size of the foramen or perhaps the relaxation of the ligaments under strain.

### The Synovial Membrane

DR. DAVID H. KLING, Los Angeles: Since the latter half of the nineteenth century the view has been held that the synovial membrane is merely a modified connective tissue devoid of special function. The synovial fluid was therefore regarded as a transudate, or a product of degeneration of the synovial lining or cartilage. Recent investigations, however, contradict this concept.

The most striking feature of the synovial membrane is the great difference in structure of neighboring areas. This is well shown in the lantern slides of a systematic method of dissection of the human knee joint. By a modified toluidin blue stain I have demonstrated metachromatic mucin granules in the cytoplasm of synovial cells, chiefly in the villi of the infrapatellar fat pads, and in the fornix, and only occasionally in the popliteal pouch. In the areas where the lining appeared tendinous, as in the lower part of the anterior aspect of the suprapatellar bursa and in parts of the lateral sides of the lining, no secretory synovial cells were found. The secretory cells were large and polygonal with a dark bluish nucleus and red metachromatic granules.

Later, Vaubel demonstrated marked polymorphism of synovial cells in tissue cultures. He confirmed the finding of metachromatic granules in the cytoplasm when using the toluidin blue stain. King demonstrated readily a Golgi apparatus in the synovial cells of normal human synovial tissue. It was absent in degenerating cells. This is a further proof that the synovial cells, which elaborate mucin, are healthy and active, and that the synovial fluid is not a product of degeneration.

These studies have led to the conclusion that the structure and function of the synovial membrane is twofold; it consists of a connective tissue sleeve in which secretory elements are interposed for the elaboration of synovial mucin. Corresponding to the difference in structure of the synovial membrane are also differences in the interchange of solutions, colloids and particles between the synovial membrane and the circulatory and lymphatic systems. The fibrous areas are capable only of absorption of molecular solutions, e. g. iodides or phenosulfonphthalein from the joint cavity at a rate corresponding to the absorption from tissue spaces. The villi and cell-rich areas contain cells which are able to take up colloidal suspensions from the circulation. Some synovial lining cells store particles of inert or reactant material. The reaction of the synovial tissue to irritation and inflammation is twofold. First there is the general reaction of the mesenchymal tissue, which consists of changes in the circulation, dilatation of blood vessels, extravasation of plasma and migration of leukocytes and later of macrophages from the circulation as well as from the tissues. The irritation provokes an increased activity and the production of larger amounts of synovial mucin. I found mucin in more than 95 per cent of all traumatic and inflammatory effusions. In turn, this hyperactivity causes a hypertrophy of the synovial lining cells. The highest degree is seen in conditions of milder irritations of prolonged duration which do not lead to destruction of the synovial membrane. The extent of the primary destruction and the subsequent reaction of the tissues varies according to the severity of the damaging agent. In septic, purulent arthritis and in severe cases of gonococcal and tuberculous arthritis, large parts of the synovial lining are destroyed in toto. No hypersecretion is possible because the secretory areas are wiped out. In less severe types, both general inflammatory reactions and hypertrophy of the synovial cells are present. In these types, joint effusions are common. Besides noncharacteristic inflammatory processes, we see in the synovial lining granulomatous formations, more or less typical of certain diseases, such as rheumatic nodules, tubercles or gummas.

## DISCUSSION

DR. J. ALBERT KEY, St. Louis: Dr. Kling's paper gives the impression that there are in the synovial lining of joints certain cells which are specifically devoted to the formation of mucin. That is something which people have been trying to prove for a good many years and dates from the time when Havers described mucin cells in joints. I have never been able to persuade myself that there was such a specific cell in the synovial surface under any conditions. I have always rather objected to the term synovial membrane because I feel that the synovial surface is not a true membrane but is simply a fault in the connective tissue on which cells have accumulated and that the structure of that surface, just as Dr. Kling has said, varies with the mechanical forces to which it is subjected. It doesn't make any difference what part of the body is subjected to friction—a bursa will form, that bursa will contain synovial fluid, and that fluid will contain mucin. If one removes the synovial membrane from the joint as completely as one can remove it, another synovial membrane will form, not by the outgrowth of specific cells from the edges of the defect but by the change of the cells *in situ*, and connective tissue cells that are left will proliferate and form a new surface. Also if a false joint is created by doing an arthrodesis, or if a false joint is created in a nonunion, a synovial surface will develop to line the cavity. With regard to absorption, the more deeply an animal is stained with trypan blue or other colloidal dye, the more numerous will be the cell elements which will take up that dye. For instance, if an animal is stained deeply enough even the cartilage cells will take up trypan blue. Also the macrophages are constantly wandering back and forth through the synovial membrane into the joint and out of the joint and they are one of the most important factors in distributing infection into the joint from the surrounding tissue and in eliminating foreign material, including bacteria, from the joint.

DR. JOHN SAUNDERS, San Francisco: I am happy to hear Dr. Key emphasize the fact that the so-called synovial membrane is not strictly a membrane. In this instance the term "membrane" is definitely a misnomer. It has not been sufficiently appreciated that the synovial lining of any one joint presents well defined differences of morphology in different regions of the same joint. The existence of these differences has led to many erroneous conclusions in the interpretation of histologic appearances both in health and in disease. I am entirely unconvinced as to the existence of specific secretory cells in the synovial membrane, as is contended by Dr. Kling. The evidence presented so far seems inadequate to establish such cellular specificity and does not fulfil those criteria whereby we recognize secretory activity elsewhere. There is as yet no irrefutable evidence that these cells constitute a part of the mechanism for the elaboration of the synovial fluid. Frankly I am unable to discover any difference between the so-called specific cell and the macrophage. In this connection one should keep in mind that the synovial membrane is essentially a mesothelial structure. The view that the synovial fluid is the product in part of transudation of serum from the vessels of the synovia and in part from the destruction of the articular cartilage has much to commend it. The work of MacConaill on the circulation of the synovial fluid deserves wider recognition because of its fundamental nature. This author has emphasized the importance of incongruity of joint surfaces and of the degree of viscosity of the synovial fluid for adequate lubrication of a joint. By reference to the theory of lubrication he has shown that the incongruity of joint surfaces established cuneiform spaces which create mechanical conditions enabling a positive pressure of the synovial fluid to develop between the opposed surfaces. In addition he has shown that the intra-articular cartilages of joints relate primarily to the synovial fluid, creating cuneiform intervals which assist in this process. The role of such cartilages is active rather than passive. MacConaill makes an interesting comparison between the menisci of the knee joint and the so-called Mitchell thrust pads. These thrust pads are a refinement of marine engineering employed when thrusts are to be carried by a film of lubricant during motions in which there is a considerable amount of gliding. Such pads or menisci increase in the higher ranges of motion the efficiency

of joints and their lubrication. It has been my custom to demonstrate this circulation and action of the interarticular cartilages to students. Goodsir pointed out in the 1860's that a joint must have incongruity—the worse the fit the better the joint, as it were. In this way only a small area is actually bearing at any one time, which allows of reconstitution of unapposed surfaces. MacConaill's work is a further elaboration of this principle. Dr. Key mentioned something about extra-articular fat simply filling up dead spaces about the joints. I object to this conception. I think it can be demonstrated that the fat plays an active rather than a passive part in joint mechanism. It should be remembered that fat is semifluid at body temperature. During movement there are changes in the capacity of a joint. Such changes in capacity permit the inward flow of the semifluid fat, which presses the synovial membrane, carrying with it synovial fluid, against the exposed surfaces of articular cartilage, lubricating them ready for the next movement. In no places can one demonstrate this functional mechanism more beautifully than in the action of the elbow or in the action of the knee joint.

DR. M. HENRY DAWSON, New York: Dr. Meyers, chemist of the Pathological Institute of the Medical Center, who has been studying the chemistry of synovial mucin, has been successful in isolating mucin in a pure form for the first time. It turns out to be not a nucleoprotein but a complex polysaccharide. This polysaccharide is not found as a normal constituent in the human serum. I believe that this will establish definitely and finally with no equivocation whatever that synovial mucin is a secretion and is not a transudate or degenerative product of cartilage.

DR. KEY: I think that this mucin is due to trituration of cells which are broken off from the surface.

DR. DAVID H. KLING, Los Angeles: Now Dr. Key and Dr. Saunders have said that they couldn't find these secretory cells. I want to ask them whether they have studied these cells with the toluidine blue stain?

DRS. KEY and SAUNDERS: No.

DR. KLING: There are others, including myself, who have studied these cells by toluidine blue and we have found mucin granules in the cells, and you will see them in my exhibit. I do not claim that the synovial membrane is a gland. I recognize the mesenchymatous origin of the synovial tissue. I do however claim that this tissue is pluripotent and contains non-differentiated cells which, under physiologic and pathologic stimuli, elaborate mucin. Such cells are also present in peri-articular tissue, and this explains the formation of bursa and ganglion after traumatic or inflammatory irritation. In two slides of a malignant synovial tumor the dual structure is pronounced. The connective tissue forms solid sarcomatous areas. The secretory cells, on the other hand, give rise to glandlike structures which are filled with mucin. Moreover, the metastases of this tumor in the lung show identical histologic pictures and thus support the conception of the dual nature of the synovial membrane.

## Gold Therapy in Proliferative Arthritis

DRS. J. ALBERT KEY, HERMAN ROSENFELD and O. E. TJOFALT, St. Louis: Seventy patients with arthritis of the proliferative type were treated with myochrysin (an aurothiomalate of sodium). Nine of them had spondylitis ankylopoietica and these were not appreciably helped by the gold compound. Of fifty-three patients with typical chronic atrophic arthritis with an average duration of over three years the results were as follows: Two became worse, six were not improved, four were slightly improved, thirteen were moderately improved, eighteen were markedly improved, three were apparently cured and seven were improved when last seen but did not return for a final examination. The gold compound was given at weekly intervals by intramuscular injections of from 0.025 to 0.1 Gm. of myochrysin until the patient received 2 Gm. of myochrysin (1 Gm. of gold). Then after a rest period of six weeks the treatment was resumed if the arthritis was still active. Toxic reactions were frequent and occurred in forty-four of the seventy patients. Most of the reactions were mild skin irritations but there were three cases of severe exfoliative dermatitis. There were no

fatal reactions. Vitamin C was given in excess during the treatment and patients with anemia were given liver or stomach extract and iron. Underweight patients were given a high caloric diet and overweight patients were given a low caloric diet. Gold therapy is dangerous and the patients must be watched carefully and the drug stopped at the first sign of a toxic reaction. It is believed that gold is the most valuable agent now known in the treatment of atrophic arthritis.

## DISCUSSION

DR. K. K. SHERWOOD, Seattle: I have used sodium gold thiosulfate for a period of four years in the treatment of certain forms of arthritis. I have used small doses, 10 mg., given intravenously at weekly intervals, until either the disease had ceased to be active, improvement ceased, or toxic signs developed. My results agree with Dr. Key's. Certainly, in the peripheral, true atrophic arthritis, it is beneficial in certain cases. I have at the same time run a control series in cases of an ambulatory character, using weekly physiologic saline placebos and I find that in this type of case approximately 25 per cent will remain stationary or get worse, while 25 per cent will spontaneously improve. Hence the 42 per cent of improved patients treated by Dr. Key and his co-workers with gold certainly indicates a definite therapeutic effect. All the severe reactions which I have seen occurred in the cases of spondylitis. Has Dr. Key found that spondylitis is especially apt to give trouble? My results agree with his in that there are no marked beneficial effects in cases of spondylitis. I am using a much smaller dose and getting approximately the same results. I wonder whether Dr. Key has tried a smaller dose, perhaps spread over a longer period of time. How frequently have routine laboratory tests, especially urine, hemoglobin, sedimentation and differential counts been made as a check on early signs of toxicity which do not give clinical manifestations? I have checked the blood in a routine manner every month.

DR. M. HENRY DAWSON, New York: The most complete report on the use of gold salts in the treatment of chronic arthritis is that of Hartfall, Garland and Goldie, published last year in the *Lancet*. In all, 750 cases of arthritis were treated, 590 of which were diagnosed as rheumatoid arthritis. These authors conclude that gold salts are the most effective therapeutic agents which we possess for the treatment of rheumatoid arthritis. However, they also report that toxic reactions developed in 40 per cent of the cases and seven fatalities due to the treatment are recorded. In a report from Australia, Parr and Shipton also report favorably on the use of gold salts. Seventy cases were treated with one fatality. We have not used gold therapy in our clinic simply because we were afraid to. If one patient out of every hundred succumbs to the treatment and 40 per cent have toxic reactions, it is obviously a dangerous form of therapy. One must be certain that the results justify the risks involved. It may be that further experience will show that such is the case. I should like to congratulate Dr. Key on his results in handling a potentially dangerous drug.

DR. PHILIP S. HENCH, Rochester, Minn.: I have just returned from a three months trip through England and Scotland. In those countries gold therapy is the form of treatment for atrophic arthritis which has elicited the greatest interest in the past ten years. It seems significant that interest in this treatment is still increasing, not diminishing. I discussed the merits and demerits of chrysotherapy with many physicians, among them Buckley, Copeman, Collins, Davidson, Goldie, Schlesinger and Tegner, as well as with Forestier and other continental physicians who were attending the International Rheumatism Conference at Oxford and Bath. I found that conservative internists and rheumatologists agreed that gold therapy, although somewhat dangerous, has produced better results in cases of atrophic arthritis than has any other single form of treatment or combination of treatments heretofore available. These men differed in their opinion on the incidence of toxicity from gold. Some noted toxic reactions of varying degrees in 40 per cent of those in which the treatment was used while others noted them in only about 10 per cent of cases. Most of the toxic reactions were of little significance. However, serious toxic reactions do occur in a small percentage of cases and in the series of 900 patients treated by Hartfall, Garland

and Goldie (*Lancet*, Oct. 2, 1937) a mortality rate of 0.8 per cent (about one in 125 cases) was ascribed to this therapy. Such a risk is much greater than that of any other form of antirheumatic treatment and places a serious obligation on the physician who chooses patients for such treatment. I believe that only those patients whose stubbornly progressive arthritis has resisted a thorough trial of the more orthodox and conservative therapy should be subjected to the treatment, at least until we in the United States have had more experience with it. The incidence of toxicity from gold has apparently been materially lowered the last two or three years by the use of doses smaller and more widely spread than those formerly employed. In general, the present program of treatment in England is to begin with small doses, injecting about 10 mg. at the first dose, either continuing with that dose two or three times or increasing subsequent doses at once to 25, 50 or 100 mg. A dose of 100 mg. is about the largest used. Injections are given about once a week till a total of 1 Gm. (occasionally 1.5 Gm.) has been given. This constitutes the first course. It is emphasized that nobody is cured or materially helped by one course alone. An interval of from ten to twelve weeks is allowed to elapse and then a second course is given. Sometimes three or even four courses are prescribed. "Cure" or marked improvement has been reported as occurring in from 70 to 85 per cent of cases. The treatment is not recommended in cases of atrophic spondylitis, hypertrophic arthritis or fibrositis. Great diligence must be used by physicians to note signs of impending serious toxicity and nobody should use this form of treatment without thoroughly familiarizing himself with such reports as those of Forestier (1935), Buckley (1936), Crosby (1936), Copeman and Tegner (1937) and particularly the report of Hartfall, Garland and Goldie (1937). Our English colleagues have accused us of neglecting to study a useful form of treatment; they believe that we too will approve of it when we have given it a "fairer" and much more extended trial than we have thus far.

DR. EPHRAIM GOLDFAIN, Oklahoma City: I began to use gold therapy as an additional measure in the treatment of chronic atrophic arthritis approximately five years ago. I use sodium gold thiosulfate in a stabilized solution. My routine procedure was to begin with 10 mg. of the gold salt intravenously, increasing the dose each week to where 50 mg. of the salt was being administered by vein each week. I found that that dose was too large and began reducing it to the point at which for a time I used an injection of 25 mg. of sodium gold thiosulfate intravenously at weekly intervals. Additional reports began to appear in the literature however about the desirability of using small doses of gold salts in other conditions. I then began to reduce the dose of gold salts and found that as good results were obtained and the likelihood of toxic reaction on the part of the patient was entirely obviated. I now administer the gold salts intramuscularly instead of intravenously. I find that given intramuscularly they cause no local reaction or induration. The dose given to the patient is 7.5 mg. twice a week so that a total of 15 mg. a week is being used. So far as I know there have been no deaths from the use of gold salts in accordance with the method thus outlined. I have not had any serious toxic reactions. Especially have I noticed that even mild cutaneous reactions are entirely obviated when the smaller doses last mentioned are being used. It is my observation and impression that the use of gold salts in the treatment of atrophic arthritis is of definite value and produces an increased percentage of improvement as compared to the treatment of these cases without gold salts. It is my feeling that gold salt therapy is an excellent addition to the armamentarium that we use in the treatment of these cases.

DR. R. GARFIELD SNYDER, New York: Dr. Key has carefully tabulated not only his successes but also his failures and his toxic reactions. He has warned us that gold therapy will not cure every case of chronic arthritis. It is my belief that gold therapy should not be used except in cases that have proved refractory to every other form of treatment. My associates and I have used gold therapy during the past three years in more than 200 cases in the Arthritis Clinic at the Hospital for the Ruptured and Crippled in New York, and in general our

results correspond closely to those obtained by Dr. Key and his co-workers. However, our results were not quite as good. This is probably due to the fact that Dr. Key used myochrysine, while we used sodium gold thiosulfate. European workers all agree that myochrysine is the most efficacious drug; it is also the most toxic. Dr. Key obtained approximately 57 per cent toxic reactions. European workers report from 40 to 50 per cent of toxic reactions, but we had only 17 per cent of toxic reactions in our clinic, and I myself have had no toxic reactions in my private cases. While Dr. Key followed the European advice with regard to giving not over 100 mg. of gold salts at any single injection, he appears to have exceeded the limit of what is usually considered a safe total dosage in any single series. In some cases he gave as high as 2, 4 and even 6 Gm. total dose to each patient. Differences of opinion exist as to what should constitute the total dose to be given in any one course of treatment. Hartfall and Garland say 1 Gm., Slot 1.2 Gm., Buckley from 1 to 1.5 Gm., Phillips 1.5 Gm., Williams from 1.8 to 2.4 Gm., Baker 2 Gm., Bach 2.5 Gm. It is obvious therefore that at the present time it is not as a general rule considered safe to give more than 1 Gm. in any single series, making a total of 3 Gm. for three series.

One cannot emphasize too strongly the point that, although gold is a valuable drug, it is also a dangerous one. The French and English rheumatologists believe gold salts to be the best single agent for the treatment of arthritis. While in this country medical opinion was hostile to this form of treatment until three years ago, I think the general attitude of the profession has been rapidly changing since then. I still cannot concede that it is the best single remedy for arthritis and I do not feel that it is advisable to use this drug in early cases that can be treated by safer methods. Toxic reactions, while usually preceded by pruritus, may appear suddenly and unsuspectedly, and for this reason constant vigilance is the price of safety when one is using this form of therapy. A severe toxic reaction may come on after a small initial dose or it may appear at any time during any series of treatments, even if there had been no symptoms of toxicity during the previous series. Occasionally one encounters a delayed toxic reaction, which may come on from one to three months after the last dose of gold salts. In my own experience the toxic reactions consisted largely of mild dermatologic reactions and gastrointestinal disturbances lasting from a week to ten days. In two cases, however, the reactions were severe. One patient had a dermatitis which lasted two and a half months. The other patient had an edema which involved the glottis and required a tracheotomy. Both patients received an initial dose of 10 mg. of sodium gold thiosulfate, followed in the first case by a second dose of 10 mg. and in the second case by a dose of 20 mg. Both patients made excellent clinical recoveries.

Gold salts have been used for the past ten years in Europe. During the first five years of their use a great deal of experimentation had to be done with regard to dosage and many fatalities resulted. Until three years ago the mortality rate in Europe was 3 per cent, but at the present time it is approximately 1 per cent. Dr. Key reports no fatalities in his series of seventy cases. We reported a series of 100 cases last year without any fatalities, but in spite of increasing experience, we have since had one death which resulted from aplastic anemia. We now question each patient carefully as to any unusual symptoms and also do a urinalysis as a matter of routine before each treatment with gold salts. In addition, we insist on a complete blood count at least once a month during the period of therapy. The exact way in which gold salts act is not known. In all probability the beneficial results observed are due in part to shock therapy, because many patients who have been given large doses develop typical chills and fever similar to those observed following the use of a foreign protein. It is interesting to note that Ken Yanagisawa and Sakae Kawai, two Japanese workers, have just pointed out that the only gold compounds therapeutically active are those which contain sulfur and in the treatment of experimental tuberculosis in guinea pigs they found that one of the compounds was just as effective when the gold was removed and the sulfur left in. In light of our recent experience, however, that it requires large doses of sulfur to produce beneficial therapeutic results in the treatment

of arthritis, the possibility that the beneficial results observed in gold therapy are due to the sulfur content seems rather remote. I should like to ask Dr. Key to express his opinion on this subject. I heartily agree with Dr. Key that every effort should be made to find a gold preparation which would be less toxic, although just as efficient as myochrysine.

DR. J. ALBERT KEY, St. Louis: Our first severe reaction was in a patient with spondylitis and that patient was in the hospital for about six weeks with exfoliative dermatitis, which was followed by furuncles. When he got out he wanted to have more gold treatments. The question of dosage is not settled. We have used the dose which is usually recommended and all our patients have had the same dose unless they were found to be sensitive and then we decreased it to a point of toleration. Our laboratory examinations were done about once a month. It would be better to do them more frequently. It isn't entirely luck that has prevented us from having deaths: part of it has been due to the fact that we have observed our cases and at the first sign of reaction we have stopped the treatment or diminished the dose. Observation must continue just as long as gold is given. Most of the reactions occur in the beginning, but they may occur in patients who have had as much as 2 Gm. of gold salt. We have had them, and quite severe ones.

#### Hydrotherapy in Osteo-Arthritis

DR. JOHN D. CURRENCE, New York: In osteo-arthritis there are certain accepted predisposing and exciting factors, although their relative importance may not be agreed on. These factors result in variable degrees of physiologic disturbances. It is only by the alleviation of this physiologic imbalance that symptomatic relief can be expected. My conclusions are drawn from the use of hydrotherapy in the treatment of more than 500 cases of osteo-arthritis seen during the past eight years. The recent observations are based on the treatment of 125 cases treated since the development of the technic described.

The physiologic reactions accomplished through the medium of water are accomplished:

1. Through the sensory stimulus to the nerves and resultant reflex.
2. By the warming or cooling action of the body, (a) by direct influence on the metabolic equilibrium, (b) by adding to or subtracting from the body heat.

The reciprocal reactions of the peripheral and splanchnic vascular beds are well known. Increased external temperature brings about a change in the blood volume ratio in favor of the peripheral structures. Actually, however, there is a reduction in the volume of the blood plasma.

The use of hydrotherapy in osteo-arthritis provides an extremely valuable adjunct to medical and orthopedic management of these cases. Judiciously planned courses of treatment, individualized to meet the specific requirements of the patient, are valuable not only in improving or restoring function but also in combating the predisposing and exciting factors of the disease. Although many patients may be benefited in their homes by improvised application of the principles set forth, institutional care is necessary to achieve the optimal result.

#### DISCUSSION

DR. RALPH PEMBERTON, Philadelphia: In general I can only approve the broad point of view Dr. Currence maintains toward hypertrophic arthritis (osteo-arthritis). I agree with him in his implications that the syndrome cannot be wholly accounted for by age and trauma alone. The intelligent use of suitable measures including physical therapy often illustrates this, since these patients may grow much older and successfully assume their subjective discomfort. There is one point in Dr. Currence's paper on which I must differ, viz. the recommendation that codeine be given to control pain. In my clinic we rarely give anodynes of any sort as they are not often needed, and codeine and morphine are never resorted to. As a matter of fact many patients when first seen have been taking acetylsalicylic acid, sometimes in large doses, and in the great majority of cases it is possible to reduce and omit it entirely within a week. I believe that any considerable use of anodynes in arthritis usually reflects unfamiliarity with the syndrome as a whole.

## Current Medical Literature

### AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (\*) are abstracted below.

Treatment of Late Abdominal Pregnancy: Report of Two Cases. A. C. Posner, New York.—p. 693.

**Placental Transmission of Neorsphenamine.**—In an attempt to measure the capacity of the placenta to transmit substances from the mother to the fetus, Snyder and Speert gave single injections of neorsphenamine to rabbits at various stages of pregnancy. In twenty-four fetuses obtained from twelve litters which were killed at various stages of pregnancy, there were striking differences in the quantities of arsenic recovered from the fetuses on examination one hour after the injection of arsphenamine. The arsenic content per fetus varied from none to 8 micromilligrams. When the stage of pregnancy was taken into consideration, it was evident that a definite correlation existed between the age of the fetus and its arsenic content. At twenty-five days no arsenic could be detected in the fetus. At twenty-seven days a small amount, estimated to be 0.25 micromilligram was found. From the beginning of the period of viability (twenty-eight days), increasingly larger amounts of arsenic were found in the fetus as pregnancy progressed; the greatest amount, 8 micromilligrams, was recovered at thirty-four days, or two days past term. In a second series of fourteen fetuses obtained from five litters in which twenty-four hours elapsed following injection the amount of arsenic in the fetus increased as term was approached. Arsenic was found in the fetus as early as the beginning of the latter half of pregnancy. The fetal portion of the placenta contained six times as much arsenic as did the maternal portion; the concentration of arsenic was only twice as great in the fetal as in the maternal portion. Gradual liberation of arsenic from the placenta to the fetus is indicated by the consistent finding of a greater amount of arsenic in the fetus twenty-four hours after injection than after one hour. The concentration of arsenic in the fetus near term approaches the level calculated to be present in the maternal tissues when definite antisyphilitic effect is exerted.

**Climate and Eclampsia.**—Dieckmann collected data as to the occurrence of eclampsia, nonconvulsive toxemia, hyperemesis gravidarum and abruptio placentae from various parts of the world. The meteorologic data have also been obtained for the various cities. Eclampsia, because of its striking symptoms and

signs, has been used as the index. Collected data show that the incidence ranges from 0 in many cities to 2.85 per cent in Algiers, Africa, and 7.2 per cent in Charlotte, N. C. The mean incidence for the world is 1 per cent, for the United States 0.66 per cent, for the British Isles 1.13 per cent, for Europe 0.68 per cent and for the rest of the world 0.52 per cent. There is some correlation, especially for the United States, between eclampsia, a high average temperature, a small range of temperature and a high measure of rainfall. The data seem to indicate that eclampsia may and undoubtedly does occur in the native who has had little or no contact with modern civilization. However, the latter with its mental strain and stress and change in diet and habits seems to cause an increase in the occurrence of eclampsia. The results warrant further investigation of the geographic distribution of these diseases as a means of determining pertinent factors, eliminating or preventing them and determining their relation to the etiology of the disease in question.

\*Acute Epidemic Superficial Punctate Keratitis. L. C. Hobson, San Fernando, Calif.—p. 1153.

**Superficial Punctate Keratitis.**—The epidemic of keratitis that Hobson describes occurred at the Veterans Administration, San Fernando, Calif., during September and October 1936. Many of the characteristics of the keratitis checked with those reported by other observers. Clinically, in the sixteen cases a violent conjunctivitis (unilateral in only one) occurred; both ocular and palpebral conjunctivae were markedly reddened, swollen and edematous, with about equal severity in each eye, in contrast to the later corneal symptoms which affected one eye to a greater degree than the other. Photophobia and lacrimation were pronounced. Pain was not severe in the conjunctival stage, which lasted from ten to fourteen days and ran a rather definite course. Repeated smears and cultures made from material taken from conjunctival culdesacs of all patients failed to reveal the presence of offending organisms. The corneal lesions consisted of minute, opaque, grayish dots (from twenty to 100), involving, for the most part, the second layer of the cornea. Some may have extended into the deeper structures. The remedies usually employed in the conjunctival stage were more or less ineffectual. Keeping the patient in a dark room proved most beneficial. Either hot or cold compresses brought some relief. When pain was unbearable the instillation of pontocaine solution or ointment was recommended.

**Radiation Therapy of Chronic Mastitis.**—Taylor and Brown divide chronic mastitis into categories: circumscribed masses which require surgical excision and mild cases of mastitis in which no active treatment should be administered. Support of the breast, encouragement and reassurance, and the elimination of fatigue and worry will usually serve to reduce the symptoms of mild mastitis. There remains a small group of cases with diffuse disease of the breast and symptoms so severe as to demand relief. If the patient is more than 40, if she has had a sterilizing pelvic operation or if there is no probability of the patient's desiring children, roentgen castration may be undertaken with the practical certainty that the symptoms will improve. If the patient desires it, a smaller dose to cause only temporary sterilization may be given. This will produce temporary relief and probably permanent improvement and the larger dose can be given later if desired. If the patient is younger and desirous of retaining her fertility and menstrual function, direct roentgen irradiation of the breast may be undertaken. Improvement probably will not be complete and some cutaneous pigmentation is to be expected.

**Injection of Alcohol for Brachial Neuritis.**—Rather than the risks of high chordotomy or the drawbacks of chronic morphinism, Saltzstein and Schreiber think that the subarachnoid

injection of alcohol for the relief of brachial neuritis may be the method of choice in debilitated persons in whom life expectancy is uncertain and the safety of major operation doubtful. The patient is placed on a tilt table. The site of injection is arched with a pillow, the patient is pushed somewhat ventrad as for spinal injections of alcohol, and the needle is introduced at the desired level. Under roentgenoscopic control, one drop of ascending iodized oil is injected. The position of the iodized oil is ascertained. If it is not lying in the region of the roots of the nerve which it is desired to bathe, the table is tilted either up or down until it is exactly in the right place. Two cases are reported to illustrate the usefulness of the injection of iodized oil preliminary to high intraspinal injections of alcohol and to show the consequent relief obtained.

**Pathologic Physiology of Exophthalmos.**—Marine believes that thyroid insufficiency (relative or absolute) and anterior pituitary hyperactivity appear to be two of the essential factors underlying the development of the exophthalmos of toxic goiter. Yet the fact that exophthalmos does not occur in myxedema and cretinism clearly indicates that other factors than thyroid insufficiency and pituitary hyperactivity are necessary. Evidence has been reported indicating a definite sex difference in the incidence of thyroidectomy exophthalmos in both man and rabbits and that an increase in the functional activity of the interstitial cells and possibly of the adrenal cortex is necessary. Thyroidectomy with its ensuing increase in the activity of the sex gland, mediated both as a direct gonad-thyroid interrelationship and as an indirect one through the pituitary, and also the parenteral administration of synthetic androgens promote the development of exophthalmos in the rabbit. Gonadectomy abolishes and cryptorchidism maintains an existing exophthalmos in the rabbit. Disturbances in calcium and phosphorus metabolism (especially high phosphorus and low calcium) affecting neuromuscular irritability appear to be necessary additional factors.

**Pressor Reaction from Inhalation of Carbon Dioxide.**—Hardgrove and his colleagues determined the pressor reactions of twenty-one normal and forty-one hypertensive persons following the inhalation of 10 per cent carbon dioxide and 90 per cent oxygen and compared these responses with those which occur as a result of the cold test. The inhalation of carbon dioxide produced an increase in the blood pressure of normal and hypertensive persons. There was no qualitative difference in the vasopressor response of normal and hypertensive persons but a significant quantitative pressor reaction was obtained when cold was applied during the inhalation of the carbon dioxide and oxygen. When the cases of hypertension were divided into those in which the hypertension was in the early or preorganic stage and those in which the hypertension was in the advanced stage it was found that the increases which were produced in the blood pressure by the application of cold were greater in cases of early or preorganic hypertension than they were in cases of advanced hypertension. This was particularly true when cold was applied during the inhalation of carbon dioxide and oxygen. The basal blood pressure was lower in cases of preorganic

hypertension than it was in cases of advanced hypertension. The average increases in the blood pressures of normal and hypertensive persons were greater when cold was applied during the inhalation of carbon dioxide and oxygen than they were when cold was not applied during the inhalation. Since carbon dioxide has a specific stimulating effect on the vasomotor centers, the definite increase in blood pressure which occurs during the inhalation of carbon dioxide and oxygen may be assumed to indicate some hypersensitivity of the vasomotor centers. When cold was applied during the inhalation of carbon dioxide and oxygen a further increase took place. This might have been caused by a reflex transmission of peripheral stimulation to a higher reactive central mechanism that was still further sensitized by the increased concentration of carbon dioxide in the blood, but the response was most likely the result of several stimuli. These observations demonstrate that a stimulus applied to the periphery (local application of cold) or applied centrally by increasing the carbon dioxide concentration in the blood increased the blood pressure of normal and hypertensive persons. They throw no light on the question as to why the hypertensive person responds to a greater extent than does the normal person.

**Cutaneous Testing for Brucellosis.**—Simultaneous intradermal tests on 163 adults with vaccine and brucellergin indicated that heat-killed vaccine produces more severe reactions than brucellergin. In the thirteen cases that reacted most severely investigated by Angle and his associates, cutaneous testing was followed by a rise in titer of specific agglutinins. Positive reactions were obtained in 9 per cent of 7,122 school children by intradermal tests with brucellergin. There was an increasing percentage of positive cutaneous reactors in successive age groups up to early adulthood. Differences in reactions of males and females were found only in the 15 to 19 year old group and then only in white children. The lowest percentage of positive reactions was found in Negro children. Of the positive reactors 79.3 per cent consumed raw milk. There was no correlation between positive brucellergin and positive tuberculin reactions.

**Venereal Lymphogranuloma.**—Shaffer and Arnold present a study of forty-six Negro women with venereal lymphogranuloma, including observations on their treatment. In cases of late involvement in which vulvovaginal ulcers are present, after some healing and elephantiasis occur, characteristic polypoid masses develop about the entrance to the vagina and around the rectum. The average age of the patients was 29 years. The commonly accepted methods of treating the disease were entirely unsatisfactory. With the introduction of sulfanilamide and its use in greatly diversified infections, it was used in this infection in twenty-two cases. The drug was given entirely by mouth, 40 grains (2.6 Gm.) daily in four doses of 10 grains (0.65 Gm.) each for one week; 30 grains (2 Gm.) daily in three doses of 10 grains each for the second week, and 20 grains (1.3 Gm.) daily in four doses of 5 grains (0.3 Gm.) each for the remainder of the time. The usual length of treatment was from one or two months. The results with such small doses have been

encouraging. Of the twelve cases in which sulfanilamide alone was used, apparent cure occurred in three, improvement in five and no improvement in two; the results in two are unknown. Of the ten cases in which there had been previous treatment (usually intradermal injections of Frei antigen, administration of antimony and potassium tartrate, treatment for coexisting syphilis or a combination of these, none of which produced material benefit), seeming cure occurred in one, improvement in six and no improvement in one; the results are unknown in two. The rapid symptomatic improvement in the majority of cases, even of severe chronic involvement, is gratifying. Longer observation will be necessary to determine the permanence of these results. The seemingly specific results may be due to action of the drug on the secondary invaders rather than on the specific virus of the disease. Sulfanilamide may be an effective weapon also in the prophylaxis of venereal lymphogranuloma.

**Tuberculin in Acneform Eruptions.**—Because certain acneform eruptions did not respond to the usual methods of treatment, Van Studdiford performed tests with old tuberculin in forty-nine of 111 cases and followed these tests with the administration of tuberculin as a therapeutic measure. Later, routine tuberculin tests were made on all patients with cystic acne who were free of pyogenic infections or menstrual disturbances. As diagnostic agents human bovine and old tuberculin were injected intradermally in each forearm, 0.1 mg. of 1:100,000, 1:10,000 and 1:1,000 dilutions being used, and a reading was made in forty-eight hours. Therapeutic injections were made into the deltoid muscle; the starting dose was 0.1 mg. of a 1:100,000 dilution. This dose was repeated and doubled every other five to seven days until 0.4 mg. of a 1:100,000 dilution had been given for two doses and a total of six doses given. Then 0.1 mg. of a 1:10,000 dilution was given by the same method until six doses had been given, after which doses of from 0.1 to 0.4 mg. of a 1:1,000 dilution were given weekly over a period of months. Some of the patients in the series have continued the injections for six months, after which a rest period was observed. Others stopped treatment after the cutaneous lesions cleared. Some of those who stopped treatment have had a recurrence of the lesions and have commenced receiving the injections again. All patients were given calcium, creosote and cod liver oil capsules as a routine tonic. Of twenty-five patients treated for sixty days or more with old tuberculin, ten were well and eleven improved; four are not included in the series because of the short time they have been under treatment. Tuberculin gives good results in the treatment of tuberculoderma; used with care it has cleared up long-existing acneform lesions and has caused no untoward effects.

Purulent Otitis Media, Sinus Thrombosis and Suppuration of Petrous Pyramid: Acute and Chronic Forms. S. J. Kopetzky, New York.—p. 626.

**Suppuration of Petrous Pyramid.**—Since the recognition and the treatment of petrosal suppuration have advanced and the mortality has been reduced to a low figure by the various types of operations, Moorhead and Baker believe that now the otologist should pay more attention to the hearing of the patient. A study of the postoperative audiograms of many of their patients shows that the preservation of hearing can be accomplished if the radical mastoid operation is avoided.

**Meningitis from the Sphenoid Sinus.**—Teed presents a historical review of the reported cases (129) of meningitis from the sphenoid sinus and gives abstracts of the reports of some of the first cases, most of which are not included in previous

monographs on the subject. Statistical reports are studied and the conclusion is drawn that while the sphenoid sinus is involved in about 15 per cent of clinical cases of sinusitis and in 33 per cent of pathologic cases it is nevertheless responsible for approximately 35 per cent of all rhinogenous intracranial complications. Evidence is presented which indicates that the spread to the meninges and venous spaces is predominantly vascular and that this extension is aided by the close anatomic relation of the vascular marrow spaces of the sphenoid bone with the infected mucosa of the sinus. The further relation between disease of the sphenoid sinus and of the pituitary body and insanity is observed, with evidence that, in certain cases of mental aberration, resolution of the infection within the sphenoid sinus is remedial. With the recent increase of interest in this subject and with the knowledge of the symptomatology and associated pathologic changes in disease of the sphenoid sinus, the author hopes that the next few years will show a decrease in the deaths from this cause, not so much from treatment but from prevention by early attack on the diseased sphenoid sinus.

**Adrenal Cortex in Childhood Asthma.**—The Pottengers analyze a group of fifty allergic crippled patients complaining of asthma who have been under treatment for one year or longer. The whole adrenal gland has been found more effective than epinephrine alone, and most effective when given with a high salt intake. The authors now utilize a semiketogenic diet which, on the basis of an adult diet, consists of approximately 2,300 calories, roughly 145 Gm. of fat, 145 Gm. of protein and 100 Gm. of carbohydrate. It is rich in known vitamins and minerals. The two main meals are built around a large, raw salad and a portion of meat consisting of not less than 4 ounces when cooked. Sugar and all foods high in carbohydrates except whole grain, fresh ground cereals, are largely eliminated. Gelatin is used, one-half ounce or more at each meal, because of its hydrophilic colloidal properties, which aid in digestion and mineral assimilation. The vitamins, other than those contained in the large green salad, are administered in the form of a high grade raw green pasture milk, malt and cod liver oil. The complete therapy used for any person depends on the results of the physical examination. Of the fifty patients treated, 84 per cent showed improvement in their allergic symptoms and physical improvement was observed in 90 per cent. Six of the thirty-five boys in the group presented nondescent of one or both testes, all six of which showed descent under treatment. Evidence of thyroid or genital disturbance was obtained in 74 per cent of the mothers of the patients. Forty of the fifty patients were taller than normal standards.

**Intoxication and Resistance to Pneumococcal Infection.**—Pickrell carried out experiments on 175 rabbits in order to determine whether alcoholic intoxication lowers the resistance to pneumococcal infection and, if it does, to discover the mechanism by which it exerts its effect. Animals well immunized to type I pneumococci were used. The experiments make it clear that the loss of immunity during alcoholic intoxication or ether or tribromethanol anesthesia is not due to the fact that the leukocytes are paralyzed but rather to their failure to emigrate. The failure to emigrate appears to be due to an effect of intoxication or anesthesia on the vascular inflammatory mechanism. In the intoxicated body the capillaries fail to respond to the presence of an inflammatory irritant with dilatation and increase in their permeability. The failure of the capillaries to react to irritants in the usual manner in intoxicated animals is the only reason for the absence of leukocytic emigration that has been disclosed by the present studies. In what manner intoxication acts to prevent the usual inflammatory alterations in the capillaries is at present obscure, but that it does so is clearly evident. The experiments emphasize the essential role of the phagocyte in protection against pyogenic bacteria even when humoral immunity is present in high degree. Pneumococci proliferated to enormous numbers in the absence of leukocytes at the site. Agglutination of the bacteria in the tissues under the influence of the antibody was evident. Although abundant leukocytes were present in the blood stream, their failure to escape permitted the progressive growth of the bacteria even in the presence of abundant antibody. The studies demonstrate that if bacteria are aspirated into the lungs during deep intoxication or anesthesia they will grow uninhibited by the defenses of the body during the entire period of unconsciousness, and this, regardless of the amount of immunity possessed by the body against the bacteria. If the bacteria are able to grow unrestrictedly during several hours, they may easily become so numerous that inflammation developing after recovery of consciousness may be unable to overcome them.

Myoplastic Thoracoplasty. E. F. Butler, A. M. Skinner, Oneonta, N. Y.; R. Douglass, Ithaca, N. Y., and C. G. Merkel, Mount Morris, N. Y.—p. 93.

**Apicolysis Thoracoplasty.**—The ideal indications for apicolysis thoracoplasty that Gale and Oatway list are a relatively good condition and clinical inactivity of the patient, a normal, a stable, or a controlled contralateral lesion, absence of severe

tuberculous or nontuberculous extrapulmonary complications, functional need for selective partial collapse therapy, thin-walled cavitative lesions of considerable size or extent, single or multiple cavities in the upper paravertebral region and bilateral apical disease which makes a bilateral partial collapse necessary. The contraindications include relatively poor condition and clinical activity of the patient, an active, an unstable or an uncontrolled contralateral lesion, presence of severe tuberculous or nontuberculous extrapulmonary complications, large thick-walled cavitative lesions, gross apicohilar fibrosis (which if displaced caudally in its entirety might cause obstruction of larger bronchi or great vessels or later require otherwise unnecessary operations to obtain satisfactory collapse), large thick-walled cavities, dense peripleural fibrosis which prevents a safe dissection and small thin-walled cavitation occurring laterally. The authors have not found a progressive improvement in their statistical results. A fair comparison of apicolysis with the paravertebral operation cannot be made, since patients subjected to the latter had less destruction of the lungs and were better risks. The unfavorable results include the failure to close some thick-walled and certain check valve cavities. The sputum was converted in a high percentage of the cases, but more sensitive tests of the bronchial secretion were not as completely influenced. The immediate mortality was probably somewhat increased by the procedure. Atelectasis occurred and persisted too frequently but can be avoided by observing the predisposing factors, by careful individualization and by decreasing the size and extent of the lysis. It can be treated by taking immediate steps to evacuate and ventilate the obstructed portion of the bronchial tree. Scoliosis has not been avoided completely, but the localization of collapse has resulted in less incarceration of the scapula. The favorable results include a greater selectivity of collapse and conservation of functioning wall of the chest and pulmonary tissue. Collapses have been most perfect in lesions with the least fibrosis.

\*Rheumatic Subcutaneous Nodules and Simulating Lesions. H. Keil, New York.—p. 261.

**Rheumatic Subcutaneous Nodules and Simulating Lesions.**—From the data that Keil presents he believes that the following principles should be established: 1. The term rheumatic nodule should be applied to lesions occurring in the course of undoubted rheumatic fever. The highest degree of clinical specificity is observed in childhood, and the rheumatic subcutaneous nodule may be said to be highly specific of rheumatic fever in this age group. 2. The specificity of the rheumatic nodule is dependent on its clinical properties and relations. The combination of pathologic changes found in microscopic examinations, while often suggestive, shows no pathognomonic characteristics and may be simulated by other lesions. 3. The true rheumatic nodule is practically always associated with clinical evidence of cardiac involvement in one form or another. 4. The typical nodule in rheumatoid arthritis differs from that in rheumatic fever in many clinical attributes and in some pathologic respects. The clinical differences appear to be more important than the pathologic differences, the latter still requiring evaluation. 5. The nodule in rheumatoid arthritis shows greater resemblances to the juxta-articular node in syphilis. 6. The conception of the syphilitic nodule as an entity rests on three features: its association with other manifestations of syphilis, the almost invariable presence of a positive Wassermann reaction and the striking response to antisymphilitic therapy. 7. The controversy regarding the relative incidence of subcutaneous lesions in rheumatoid arthritis and in syphilis is clarified by the realization that both varieties of nodules occur but that their respective incidence will be governed largely by the type of material under observation. 8. The pathologic appearance of a rheumatic nodule, as observed in the ordinary microscopic examinations, is not pathognomonic of a single disease. How far the supravital studies will provide criteria for the differentiation of the various nodules is still problematic, but it is a method worthy of extended investigation. Caution is advised in drawing etiologic conclusions on the basis of morphologic resemblances.

**Lead Poisoning.**—Gray and Greenfield cite two cases illustrating the dangers of deleading in acute lead poisoning and four cases illustrating the increased lead stream with a high calcium regimen. An adequate phosphorus intake is important for the formation of the insoluble dibasic lead phosphate which is stored in the skeletal system as the insoluble tertiary lead phosphate. Furthermore a large intake of phosphorus is necessary for normal bone metabolism and for the formation of an insoluble lead phosphate in the intestinal tract. The reabsorption of lead which may be excreted in the intestinal tract may be prevented if there is sufficient phosphorus in the diet. Under normal conditions the insoluble tertiary phosphate of lead is deposited in the bony tissues. Since this salt is retained as a skeletal deposit, the bones gradually remove lead from the circulating blood. The two processes of storage and excretion take place during the absorption of lead and continue after absorption has ceased, until practically all the lead in the body is held by the skeleton. While this state of affairs exists the stored lead is apparently harmless and symptoms of intoxication disappear. In isolated instances deleading may be helpful when the question of lead poisoning is considered in a differential diagnosis. The importance of deleading in the differential diagnosis is the finding in biologic materials of lead below that which may be considered normal. If after a period of deleading therapy (from seven to ten days) lead is found in quantities which fall within the range of normal limits it may be excluded as the agent responsible for the symptoms. The exception may be the individual who has had a short period of exposure to the absorption of lead. Deleading may be of value occasionally in continued litigation to determine whether an abnormal storage of lead exists and is responsible for the continued subjective symptoms in the absence of objective observations. If after deleading for a suitable period the amount of lead excreted in the biologic materials is within normal limits, the symptoms

may have been due to the toxic effects of the lead absorbed during a previous exposure and not to waves of liberation. In a case of acute lead intoxication, deleading therapy should not be attempted because of the danger of neurologic complications. When deleading is decided on, it is advisable to continue such treatment for no longer than seven or ten days. Occasionally there may be gastrointestinal disturbances associated with the administration of drugs and the acidosis produced during this form of therapy. A high calcium regimen is probably the best means of rapid deleading. The danger of neurologic complications during deleading, even among those in whom there is no acute lead intoxication, is a hazard which can be detected early only when the patient is under careful institutional observation.

**Relapses After Hypoglycemic Shock.**—Horwitz and his associates state that in sixty-seven psychotic patients treated with insulin there were thirty-one complete and social remissions (twenty recovered and eleven were much improved). Most of the patients who recovered were sick for less than one year. Eight relapses occurred in these thirty-one patients. Six of these were from the group of twenty considered recovered and two were from the group of eleven considered much improved. Of the fifteen women who recovered and the five who were much improved relapses occurred in seven. Two of the seven relapses occurred within a month after the patients left the hospital; the others occurred three, four, seven, ten and ten months, respectively. Of the eight patients in whom relapse occurred, two were retreated and again reached their maximal level of improvement (both of them have been on parole now for about seven months), four are still receiving their second course of treatment and again seem to be improving and two have shown no favorable response to the second course. No criteria are available as to the type of patient in whom relapse will occur.

**Sodium Amytal in Psychogenic Amnesia.**—Herman restored the memory of six persons with hysterical amnesia by giving sodium amytal intravenously. Their memory was restored within a few minutes. In each case other methods, including hypnosis, had been tried without success. Many theories have been evoked to explain the action of sodium amytal in producing its psychologic effect. The most likely theory is the physiologic explanation that sodium amytal is a cortical depressant and tends to diminish the normal inhibitory action of the cortical cells.

- \*Studies on Immunizing Substances in Pneumococci: VII. Response in Human Beings to Antigenic Pneumococcus Polysaccharides, Types I and II. L. D. Felton.—p. 1855.
- \*Id.: VIII. Report on Field Tests to Determine Prophylactic Value of Pneumococcus Antigen. G. M. Ekwurzel, J. S. Simmons, L. I. Dublin and L. D. Felton.—p. 1877.

**Prophylactic Value of Pneumococcus Antigen.**—The present study by Felton and his associates is a continuation of the investigation of the activity of the antigenic polysaccharide of the pneumococcus in human beings and an analysis of the

prophylactic value of a pneumococcus antigen used in field tests on CCC volunteers. A test is described for white mice which apparently determines the presence of reacting substances and consequently may be used to assure an antigen suitable for injection without reactions in human beings. A type I antigen, shown to be specific for white mice, produced antibodies in children against type II of almost as high a titer as against type I organisms. Conversely, one preparation of specific type II antigen stimulated type I antibody in only one of five children tested. In adults the same specific antigens produced heterologous immunity. A test of thirty-five subjects one year after injection of 2 mg. of polyvalent antigen showed the presence of type I serum antibody in 51 per cent and of type II antibody in 77 per cent of the group. In all, 281 persons varying in age from birth to 79 years have been inoculated and tested for serum antibodies against type I and 276 against type II pneumococci. There was no transfer of the antibody to the baby from two mothers who had been immunized before delivery. All babies less than 1 year of age and six adults in the type I group and two in the type II series showed no antibodies either before or after the injection. All others, following a single injection of 2 mg. of antigen, showed an increase, although varying in amount, of serum antibodies against both type I and type II pneumococci. An analysis of the records of the present experiments suggests that this or a similar antigen may prove to be a useful tool for the control of the incidence of pneumonia, as in two groups of CCC camps, as compared with control groups, the incidence was reduced from 7.28 to 4.34 and from 15.69 to 1.73, respectively, per thousand years of life. The present experiments provide no indication as to the length of time for which the inoculations of antigen may influence the pneumonia morbidity rates. There is some indication that the antigen may be most effective for adolescents and that it loses its effectiveness with advancing age. There was no satisfactory evidence found to show that the antigen will lower the incidence of respiratory conditions other than pneumonia.

**Gastrointestinal Ulcers and Cerebral Lesions.**—Oppen and Zimmerman give the clinical histories and postmortem observations in twenty-two cases showing ulceration, erosion or malacia of the upper part of the digestive tract (esophagus, stomach or duodenum). Lesions of varied etiology were found in the brain of each of the twenty-one cases that came to necropsy. In one additional instance the brain was not examined but the clinical symptomatology pointed to organic cerebral involvement. These lesions were localized as follows: the nuclei of the interbrain in sixteen instances, the midbrain in two instances and diffuse cerebral, chiefly cortical, involvement in three instances. In the three latter cases the diencephalic nuclei were spared. The gastrointestinal lesions in cases of cortical and mesencephalic involvement are probably mediated through the hypothalamic nuclei. Two cases are described in which injury to the diencephalon and mesencephalon was not complicated by lesions in the digestive tract. Such instances emphasize the present lack of knowledge concerning the pathogenesis of lesions of the alimentary tract.

**Tuberculosis and Sulfanilamide.**—Buttle and Parish found that sulfanilamide inhibited the course of generalized tuberculosis in guinea pigs infected with the human strain of the tubercle bacillus. Their results are less striking than those of Rich and Follis (1938), possibly because of a difference in the tubercle strain. The drug had little influence on the course of infection in guinea pigs and none in rabbits when a bovine strain was used. Further prolonged experimental investigations with sulfanilamide and other preparations are necessary under controlled conditions, and special attention should be paid to the toxicity of the drugs employed.

\*\*\*Sprained Ankle." I. S. Smillie.—p. 692.  
The Streptococcal Diseases. S. Thomson.—p. 695.  
Recovery and Rehabilitation. J. Cunningham.—p. 712.

**Sprained Ankle.**—Smillie states that full dorsiflexion is essential for sprained ankle and is best attained by the patient who pulls strongly on the two ends of a length of 1 inch strapping which has been passed in the form of a loop round the foot. The adhesive side of the strapping crosses the sole in the region of the first metatarsal head. While the patient is doing this, a piece of piano felt is shaped to fit in front of and below the lateral malleolus and its bulk is reduced and efficiency increased by beveling the periphery. Three bands of the 1 inch strapping are used for a stirrup type of bandage. These bands overlap one another and are applied parallel to the long axis of the limb. Their overlapping breadth extends from immediately posterior to the base of the fifth metatarsal to the lateral aspect of the fibula. Each band should be applied until the maximal tension is obtained. The upper ends of the three stirrups are secured with two or three circumferential bands of strapping. The felt pad is now placed in position under the

strapping, in the gap between the strapping and the skin. One or two bands of strapping increase the tension on the strapping by being applied circumferentially round the stirrups at the narrow part of the ankle above the medial malleolus. Thus are the artificial ligaments completed. An elastoplast type of bandage is now applied under moderate tension from the roots of the toes to just below the knee. This prevents edema, increases the support and prevents the strapping from slipping. There should be no undue pressure on the base of a prominent fifth metatarsal. The patient is encouraged to use the ankle freely. There is no pain and the foot is stable. At the end of a week a change of support will be necessary, especially if the patient has exercised freely. Healing is usually complete in three weeks.

Spontaneous Hemothorax. K. M. A. Perry.—p. 829.

**Thyroidectomy for Cardiac Pain.**—Twelve patients were relieved of severe angina of effort and spasmodic angina by thyroidectomy. Bourne and Ross believe that the length of time (from three weeks to twenty-six months) that elapsed since the operation proves that this measure is of great and lasting benefit in appropriately chosen cases. Two patients died, one of syncope three weeks and one of coronary thrombosis seven months after the operation. The type of pain most likely to be benefited by thyroidectomy is that of true organic origin, of such severity as to incapacitate the patient and constantly growing worse. Patients with advanced cardiovascular disease are not desirable subjects for thyroidectomy. Adiposity is a contraindication to thyroidectomy, just as thinness is a definite indication. After-treatment must be controlled carefully in order to obtain the best results. Myxedema develops if such patients are completely deprived of thyroid, but if they are too heavily dosed with thyroid extract the pain returns.

**Macrocytic Anemia and Erythrocyte Fragility.**—Dyke and Young describe the common features in six cases of anemia of the macrocytic type. These features are (1) anemia with hemolysis shown by bilirubinemia and a serum van den Bergh reaction of the indirect type, (2) increase in the fragility of the erythrocytes, (3) increase in the mean diameter of the erythrocytes with a consequent high color index, (4) protracted course with remission and relapse, (5) abnormal activity of the hemopoietic system (shown by the presence of numerous nucleated erythrocytes and reticulocytes and by hyperplasia of the bone marrow) and (6) moderate splenic enlargement with endothelial proliferation and phagocytosis of the erythrocytes. This macrocytic hemolytic anemia unresponsive to liver therapy has been identified with congenital acholuric jaundice of the Chauffard type. Actually, the only striking resemblance between them is fragility of the erythrocytes. Their points of dissimilarity are far more numerous. The response to splenectomy of these two types of hemolytic anemia points strongly to the conclusion that

they bear no essential relation to each other. In the Chauffard type the effectiveness of splenectomy has been recognized and the operation does with reasonable certainty bring about disappearance of the symptoms, whereas, from the authors' results in the present series, its value seems doubtful in the acquired type of hemolytic anemia under discussion. Its justification in this condition is debatable.

Treatment of Pneumonia. A. Holmes à Court.—p. 555.

Treatment of Peptic Ulcer by Continuous Drip Method. M. M. O'Brien.—p. 559.

**Types of *Corynebacterium Diphtheriae*.**—Wilson and Goldsworthy isolated 200 strains of *Corynebacterium diphtheriae* from 325 individuals at the Royal North Shore Hospital. Of the 200 patients 109 (five died) were infected by the grave type of *Corynebacterium diphtheriae*, thirteen (one died) were infected by the intermediate type, forty-seven (one died) were infected by the grave type and thirty-one (none of whom died) were infected by atypical strains. Twenty-three strains have been isolated from eighteen patients with malignant diphtheria. Twenty-one cases were of the grave type, in which there were twelve deaths; one was of the intermediate type, in which the patient died, and the last was an atypical type in a patient who recovered. The grave and intermediate types caused on the average more severe disease than the mild type. The relative merits of Löfller's and Clauberg's mediums for the recognition of *Corynebacterium diphtheriae* and of Clauberg's medium and of two kinds of blood agar for the determination of type are discussed.

### Sedimentation Rate and the Erythrocyte Count.—

Schuster studied the effect of the erythrocyte concentration on the sedimentation rate on 121 individuals. Citrated blood was found to give more consistent results than oxalated blood. In the choice of a tube the diameter (within wide limits) and cubic capacity may be disregarded, but it is essential to have the same height of blood column for a series of tests; 100 mm. is a serviceable height. Polycythemia has a retarding effect on the sedimentation rate and it may disguise a pathologic condition of the blood. Anemia has an accelerating effect, which is magnified in conditions already causing rapid sedimentation. Anemia is occasionally associated with a very slow sedimentation rate. At present the association cannot be attributed to any specific type of anemia. Recovery from anemia with a subnormal sedimentation rate may be associated with a rise in the sedimentation rate. No charted system of correction for changes in the blood count is satisfactory. For special cases and research work the blood count may be adjusted to a standard concentration (say 5,000,000). In conclusion the author states that the sedimentation test as it stands is a useful but crude test for ordinary clinical work; for special investigation it should be done according to laboratory standards of technic and with a proper understanding of the controlling factors, such as the blood count. It is a complicated reaction and not a quantitative analysis. It is sensitive to so many circumstances inside and outside the body that the numerical result should be interpreted with judgment and in relation to the other biologic reactions of the patient.

\*Treatment of Acute Meningitis with Sulfanilamide. L. Tixier.—p. 609.

Disturbances in Acid-Base Equilibrium in Rickets and Tetany. T. Giza.—p. 633.

**Sulfanilamide in Acute Meningitis.**—Tixier, in his service at a children's hospital, employed sulfanilamide with good success in the treatment of cerebrospinal meningitis of various origins. The sulfanilamide preparation employed was para-amino-phenyl sulfamide (1162 F), which is active in vivo and in vitro. The author regards the oral route as the best method of administration and thinks that the intraspinal administration should be reserved for extremely severe cases. The duration of the treatment varies according to the causal agent of the meningitis. René Martin ascribes considerable significance to the sulfanilamide concentration in the cerebrospinal fluid, maintaining that the concentration must be 4 mg. per hundred cubic centimeters. Tixier, however, obtained an extraordinarily high percentage of cures in various types of meningitis without ever testing the sulfanilamide content of the cerebrospinal fluid. Regarding the prophylactic use of sulfanilamide he says that epidemics of cerebrospinal meningitis have been arrested by giving sulfanilamide to exposed persons, such as children, who attended schools in which cases of meningitis occurred. Moreover, he thinks that the treatment with sulfanilamide is justified in cases of suppurating otitis media which do not drain in the usual length of time or in operations on the mastoid which do not cicatrize rapidly, or in other contagious diseases such as grave tonsillitis. Serious complications, especially suppurating meningitis, can thus be reduced to a minimum. The author says that in hundreds of patients treated he never observed a complication of sufficient gravity to necessitate a change in treatment. The cyanosis of the lips and the extremities disappears spontaneously even though the doses of sulfanilamide have not been reduced. In the second part of this report the author takes up separately the various types of meningitis. Under the heading of streptococcal meningitis he first discusses those forms which are secondary to auricular disorders and then the primary forms. Then he discusses and illustrates by case histories the effect of sulfanilamide on meningococcal meningitis, on meningitis without visible microorganisms and on pneumococcal meningitis.

\*Limits of Cardiac Activity in Healthy Persons and Patients. Gunther-Zaeper.—p. 1583.

Massive Uterine Gangrene After Delivery. R. Schockaert and J. Brenez.—p. 1590.

### Limits of Cardiac Activity in Healthy Persons and Patients.—

Gunther-Zaeper points out that nearly all the methods utilized so far for the estimation of the functional activity of the heart lack exactness. The author shows (1) that the index of the heart minute volume must be utilized in order to estimate the effective functional activity of the heart and (2) that the oxygen requirements and its transport must be the function of this index, since the transport of oxygen is the most important role of the circulation of the blood. The determination of the absorption of oxygen according to the formula of Fick gives as product the heart minute volume index by the arteriovenous difference in oxygen. This formula shows clearly the significance of the heart minute volume index and its limits in determining the maximum absorption of oxygen and thus the physical capacity. The author established a new method closely related to the procedures of Fick and Plesch, with which he made a series of determinations of circulatory exchanges and of the heart minute volume index. The subject is connected with a metabolism apparatus of Knipping in order to determine the absorption of oxygen. During the work test a stopcock is turned to make the person breathe according to the method of Plesch by means of a mask, the nitrogen passing into a rubber container; in this manner is effected an exchange between the blood which flows from the right side of the heart to the lung and the gaseous mixture arriving in the rubber container, until equalization of pressures

is effected. The venous alveolar air thus obtained is immediately brought into contact with a specimen of blood, withdrawn directly after the assay in a tonometer at the temperature of the body. After the equalization of the gaseous tension the oxygen content is examined in the apparatus of van Slyke. By this procedure the oxygen saturation of the venous mixture of the right side of the heart can be determined indirectly. If after that the arterial saturation is determined either in the arterial blood or in the venous blood that has been saturated with oxygen, it is possible to calculate the difference between the oxygen contents of the arterial and venous bloods. By dividing the figures obtained for the absorption of oxygen by the difference in the oxygen contents of the blood of the right side and that of the left side of the heart, the figure for the heart minute volume index is obtained. The author describes observations with this method on persons who have undergone physical training, on persons who have not undergone such training and on persons with cardiac disorders. He shows that the determination of the respiratory volume and the estimation of the activity of the heart and of the circulation, with the described method, permit a qualitative estimation of the functional capacity of the circulation and the heart.

- \*Arrhythmia of Patients with Hypertension. A. Dumas.—p. 555.  
Complete Arrhythmia and Rheumatism. L. Gravier and A. Tourniaire.—p. 563.

**Arrhythmia with Hypertension.**—According to Dumas, the severe hypertensions are in general incompatible with arrhythmia. Only extrasystoles, either sporadic or grouped together, are encountered. This extrasystole annoys patients considerably and its treatment is difficult. Complete arrhythmia, on the other hand, is well tolerated by the majority of patients with hypertension. Moreover, recovery from it is accompanied by a reduction in tension; subjectively it is better tolerated than extrasystolic arrhythmia; it does not give rise to pain and when it is accompanied by a slight cardiac insufficiency it can easily be remedied by medication with suitable cardiac tonics. Complete arrhythmia is preferable to the menacing gallop of a regular heart, which maintains a blocked hypertension, capable of provoking either a cerebral hemorrhage or a sudden failing of the heart.

\*Polyglobulism Provoked by Extracts of Anterior Lobe of Hypophysis. Prove Existence of Hemopoietic Hormone. J. Flaks, I. Himmel and A. Zotnik.—p. 1506.

**Polyglobulism and Anterior Lobe of Hypophysis.**—Flaks and his associates state that clinical and experimental observations cited in a previous report indicated that, under physiologic conditions, the hypophysis regulates the hemopoiesis. They attempted to prove that this hemopoietic action of the hypophysis depends on a hormone which differs from the hormones already known. In order to prove the existence of an especial hemopoietic hormone they made investigations in two directions: (1) by ascertaining the atrophy of the hemopoietic tissue of the bone marrow and of the morphogenic elements of the blood, following the ablation of the hypophysis and their reactivation by the administration of hypophysial substance; (2) by provoking a hemopoietic hyperactivity by surcharging the normal organism with supposedly hemopoietic elements. The experiments were made on rats. Discussing the technic they say that the hemoglobin was determined by means of the hemoglobinometer of Hellige and the number of erythrocytes with Thomas's apparatus. The reticulocytes, which were colored with brilliant cresyl violet, were counted in the humid chamber. The bone marrow was extracted from the femur immediately after the animal had been killed. The hypophysis was extirpated after trepanation of the base of the cranium by means of a small vacuum pump. Observations on the variations in the blood elements in normal rats show that the number of erythrocytes never exceeds 9.5 millions.

Consequently, the authors regard as polyglobulism those values of erythrocytes which exceed 10 million. Polyglobulism is the test for the demonstration of the hemopoietic hormone. Hypophysial substance was administered to hypophysectomized as well as to normal rats. On the basis of these and of earlier experiences the authors reach the conclusion that it is justified to admit the existence of a hemopoietic hormone in the hypophysis.

### Schweizerische medizinische Wochenschrift, Basel

68: 1153-1180 (Oct. 15) 1938. Partial Index

Cutireaction with Diphtherial Toxin, Test of Sensitivity to Diphtheria. T. Reh.—p. 1173.  
Insulin in Nonschizophrenic Psychic Disturbances. J. E. Staehelin.—p. 1175.

**Renal Function in Scarlet Fever.**—Gautier reports studies on azotemia in fifty children. He lists the average azotemic values during the first five days, from the sixth to the tenth day, from the eleventh to the fifteenth day and from the sixteenth to the twenty-first day. This list indicates that the values were highest during the first five days. However, this early azotemia has no connection with the scarlatinal nephritis. Moreover, the general condition in the course of scarlet fever seems to exert no great influence on the azotemia. The author also cites observations on albuminuria and on the elimination of urea in the urine of children with scarlet fever. He says that he performed Volhard's test systematically in twenty-six children with scarlet fever. On the basis of the results he differentiates seven groups of patients. In the first group, which comprised six children, the test was at once normal. In the second group (four children) the test revealed abnormal results with regard to the diuresis. However, repetitions of the test revealed gradual subsidence of the functional disturbance. In the third group (one case) the first test revealed abnormal conditions as regards the diuresis as well as the dilution. In the fourth group (seven cases) the test revealed abnormalities in the diuresis and the concentration. The functional disturbance disappeared before the end of the scarlet fever in all these cases. In the fifth group (two cases) the test revealed abnormal diuresis, concentration and dilution. In the sixth group (three cases) the test still revealed abnormalities during the fourth repetition. In this group the clinical observations gave no satisfactory explanation for the abnormal outcome of the test. The seventh group includes the patients with previous renal lesions caused by a former nephritis. The cases cannot be compared with the others. The author reaches the conclusion that Volhard's test, if performed systematically, often reveals in one of the stages of the disease a functional disturbance of the kidney which is usually mild. The results obtained with the two methods of renal examination (study of azotemia and Volhard's test) confirm that it is necessary to keep the renal function under careful observation in the course of scarlet fever.

### Bollettino d'Oculistica, Florence

17: 693-800 (Sept.) 1938. Partial Index

\*Behavior of Ocular Tension in Course of Hypoglycemic Coma. G. Ciotola.—p. 738.  
Estrogenic Substance in Therapy of Gonorrheal Conjunctivitis. D. Borioni.—p. 776.

**Ocular Tension in Hypoglycemic Coma.**—Ciotola observed the ocular tension in the course of hypoglycemic coma in eleven patients with schizophrenia. Determinations of the tension were made at half hour intervals during the first four hours in the course of various attacks of insulin coma. Ocular hypotension was present in all cases. In some it amounted to 12 mm. of mercury. According to the author,

ocular hypotension is proportional neither to the amount of insulin which is administered to the patients nor to the amount of sugar in the blood in the course of the shock. The behavior of the factors which regulate the ocular tension is similar in diabetic and hypoglycemic coma with the exception that the blood pressure is diminished in the former and increased in the latter. In both cases the hypotonic factors are the loss of water of the body with consequent thickness of the blood and increase of the osmotic colloidal pressure. A diminished blood supply of the eyeball and the presence in the blood serum of substances which are toxic for the capillaries of the eye are hypotensive factors of secondary importance. In the course of hypoglycemic coma two factors which follow an opposite direction are present. They are the aforementioned hypotonic factors on the one hand and the increased blood pressure on the other. The latter tends to prevent intra-ocular hypotension. When the former factors predominate over the latter, which is in the majority of cases, ocular hypotension takes place. In the course of diabetic coma the hypotensive local and general factors, including the local and general blood pressure, which is diminished, tend to the production of ocular hypotension, which takes place in all cases of the condition.

**Estrogenic Substances in Skin.**—Silvestroni's experiments were made in an effort to ascertain the presence of estrogenic substances in irradiated skin and the relations between estrogen and androgen. He experimented in various lots of adult female castrated rats. He found that estruation does not appear in adult female castrated rats after injections of (1) extracts of irradiated skin of adult male rabbits and male rats which had had repeated progressive ultraviolet or roentgen irradiations on the back, (2) of extracts of the whole testicle of adult animals, (3) of liposoluble or hydrosoluble testicular preparations and (4) of transplantation of testicles. Testosterone alone does not induce estruation, which appears during the first two or five days in the course of the associated treatment of testosterone and estrogen and then stops. According to the author the skin irradiated by either ultraviolet or roentgen irradiations does not contain estrogenic substances. When the latter are present in certain organs, especially in the testicle of certain animals, they originate in disintegrated estrogen which is taken in the food and transformed by the body.

**Diagnosis of Evolution of Pulmonary Tuberculosis.**—Gómez and his collaborators followed the results of the sedimentation speed of the erythrocytes and of Vernes sero-flocculation test in 200 patients suffering from pulmonary tuberculosis. Both tests show the evolution of the pulmonary tuberculous lesion and give parallel results in the majority of cases. However, the resorcinol flocculation test shows aggravation or amelioration of the pulmonary lesion earlier than the sedimentation test. Negative results of the flocculation test in the presence of positive results of sedimentation show a favorable evolution of the pulmonary lesion in the near future. The opposite also takes place. Syphilis and pregnancy have no influence on the results of the flocculation test. Both conditions cause acceleration of the sedimentation of the erythrocytes.

**Experimental Sarcoma from Radium and Mesothorium.**—Uehlinger and Schürch carried out in the course of seven years 107 experiments in rabbits in which a mixture of 0.005 mg. of mesothorium in petrolatum was placed in the thoracic cavity, the cavity of the shaft of the femur, the spleen, the liver, the stomach wall and the testis. Of the twenty-one rabbits in which implantation was made into the femur, fourteen exhibited a metastasizing sarcoma; of the three in which radioactive substance was placed in the spleen, one; of the five with implantation into the liver, one; of the eight with implantation into the gastric wall, two; of the seven with implantation into the testicle and nine into the pleura, none. The lethal period for bone sarcoma vacillated between twenty-one months and fifty months, for sarcoma of the internal organs between twenty-one months and twenty-nine months. It appeared that the carcinogenic property was equally shared by the pure alpha, beta and gamma rays. However, the sarcoma developing after the implantation of radioactive substances is to be regarded as the result of collective irradiation. The pure, free alpha mesothorium rays possess equal cancerigenic properties with radium so far as the latent period and incidence of tumor formation are concerned. The variation in the dose of mesothorium between 0.0001 and 0.005 mg. had no effect on the frequency of tumor formation or on the latent period. The effect of the radioactive substances was primarily on the connective tissue and only exceptionally on epithelial structures. With the exception of the central nervous system, no predisposition was noted on the part of any organ. The radiation sarcoma corresponds biologically and histologically to the spontaneous sarcoma. The authors predict that with the increase in the radiation treatment of tumors there will be a corresponding increase of sarcomas as the result of radiation damage.

**Chronaxia in Surgery.**—Osawa and Nagai have investigated chronaxia values in 683 patients with brain, spinal cord and peripheral nerve lesions. The observations were confirmed in most of the cases at operation. Chronaxia values in mild pathologic alterations showed a diminution or an insignificant increase, whereas in far advanced pathologic lesions the increase was great. Chronaxia values of peripheral nerves frequently are definitely increased. Changes were observed both in brain and in spinal cord lesions. However, in brain lesions they are insignificant. Chronaxia determinations enable one to make a localizing diagnosis of the lesion. The extent of the lesion and its right-sided or left-sided localization are possible in the injuries of the peripheral nerves. Chronaxia determinations are particularly valuable in cases in which the clinical symptoms are not clear. Chronaxia observations were negative in cases of simulation and neurosis. The authors believe that this method permits of more accurate diagnostic determinations than the previous methods.

**Alimentary Toxicosis in Nurslings.**—Bayer discusses the treatment of the severest form of alimentary toxicosis, the form in which the toxic symptoms are completely developed and in which there are signs of cerebral disturbances, such as

dulled sensorium or complete stupor; retardation in the conduction of pain and in the defense reactions; uncoordinated movements of the eyes; instead of vigorous crying, low whimpering and unmotivated loud cries; and slow, dragging movements of the extremities. In the seventeen cases on which the author made his observations there were three fatalities. The age of the child is a determining factor in the prognosis of alimentary toxicosis: with increasing age, the danger to the life decreases. That the previous nutrition is an important factor in estimating the severity of the process is proved by the fact that the majority of the nurslings had received no breast milk at all and others had received inadequate amounts of it. The author says that, like all severe intoxications, alimentary toxicosis should be treated in a hospital. His therapeutic efforts aim at preventing a further loss of weight, rapid detoxication and the prompt absorption of fluids. He regards it as advisable to leave the gastrointestinal tract strictly alone for a while, alimentation by mouth being stopped for from twelve to twenty-four hours. The first alimentation consists of a modified Ringer's solution, small quantities of which (20 or 30 Gm.) are given at first every hour, but later at longer intervals. Then the alimentation with Ringer's solution is changed to feeding with whey and a 6 per cent rice gruel, which are mixed in a proportion of 1 and 2. Sugar is not added to this mixture. The author is of the opinion that caloric foods such as protein, fat and carbohydrate should not be given too early by mouth. Fats and proteins in the form of breast milk or buttermilk are only slowly added to the whey-gruel mixture. At first the nursling is given only one-third breast milk but gradually three feedings of whole breast milk and two feedings of half buttermilk with 5 per cent sugar are introduced. The author says that the nutritional intake is slowly increased because inanition is no longer feared as much as it was formerly. Moreover, during the first days of the treatment the infusions are the indispensable factor in the treatment. The nurslings are given by intravenous injection a mixture of Ringer's and of a dextrose solution. This mixture is always freshly prepared. The more severe the intoxication, the smaller should be the amount of dextrose in the solution. The infusions are continued beyond the end of the fasting period, but they are gradually decreased as the oral intake is increased. In the first few days from four to six infusions of from 50 to 100 cc. each are given during each twenty-four hour period. The infusions are given mostly into the cranial veins, but they can be given also into the veins of the dorsum of the foot and hand. If during the severe collapse it is too difficult to reach a vein, the first injection may be made into the longitudinal sinus.

**Rounded Back and Funnel Chest.**—Stolte says that the majority of investigators regard the "rounded back" as the result of a deficient muscular development. It cannot be denied that a rounded back may be the result of a weakness of the skeletal musculature, but he does not think that this applies to all cases. He raises the question whether the weakness of the musculature and the fatigability of such children may not perhaps have another cause. He points out that the entire habitus of these children, with their narrow thorax, their rounded back and their prolapsed abdomen corresponds to that of the patients who, as the result of an enteroptosis, develop a drop heart. Moreover, the observations in the course of roentgenoscopy suggest a malproportion between the growth of the heart and of the vertebral column, and the rounded back seems to act as a compensatory mechanism for this malproportion. Good care and nutrition occasionally make up for the retarded development of the heart and, if this is so, the rounded back has a tendency to disappear. In the second part of his paper the author discusses the development of a funnel chest. After citing the two generally accepted theories of the development of a funnel chest he describes his own observations, which convinced him that the traction of the abdominal muscles, particularly the proper function of the abdominal rectus, is of great importance for the development of the thorax. He shows that this muscle represents, in a way, an elastic, extraordinarily adaptable prolongation of the sternum, which by its traction is capable of compensating the depression of the sternum. If this muscle is weakened, the diaphragm alone acts on the sternum and thus the funnel chest is produced.
